In qualitative research generally—and grounded theory studies in particular—an additional form of logic, **abduction**, is also practiced ([Bryant, 2017](#); [Hadley, 2017](#)). Abductive reasoning channels one's ability to infer a well-fit, plausible conclusion based on available data and to eliminate ill-fit conclusions along the way. While it cannot produce a neat or tidy logical proof, abduction can offer solid reasoning for how one arrived at one's conclusions. Abductive reasoning, such as depicted in Babchuk and Boswell's theory-tracker tool (see *Grounded Theory*, this volume), demands that a researcher iteratively induce and deduce as data are collected and analyzed. Data that ground a theory are examined through a filter of possible/plausible theoretical explanations; from there, the explanations that lack adequate support are abandoned until a well supported or 'saturated' theory can be achieved—one that never loses sight of the need to be 'fit' to the data collected.

Generalizability and transferability

Unlike a quantitative approach, which aims to generalize results from a sample to a population, a qualitative approach seeks nuanced conclusions about a relatively small sample and is not explicitly designed to extend findings to the general population. Nevertheless, a qualitative researcher may assert some generalizations about the sample, or about the application of a particular theoretical framework to a research problem. Thus, it would be an oversimplification to say that qualitative projects do not generalize—they do, but not in the same way that quantitative projects do, and not nearly as much. In [Lincoln and Guba's \(1985\)](#) iconic work on trustworthiness, they used the term *transferability*, a term which in qualitative research loosely parallels that of *generalizability* in quantitative research, and they suggest strategies to achieve it (see for example, [Merriam and Tisdell, 2016](#)). It is therefore incumbent on qualitative researchers to explain how their findings do and do not apply to other samples or sub-populations, as well as to reflexively critique their own methods and assumptions. Moreover, qualitative researchers must document these decisions and assumptions through an audit trail, as described next.

Philosophically, qualitative research departs from quantitative and other positivist-influenced approaches in that the researcher is considered the "instrument" of research ([Creswell, 2014](#), p. 185) and can be critiqued in this capacity. One way these assessments are undertaken is to evaluate the **audit trail** chronicling the research process. In the event of an audit for any reason, the researcher needs to be able to produce evidence and documentation of each step of the data collection and analysis. This could be in the form of voice memos, correspondence with an advisor as major decisions are taken, read-only data sets that have not been emended, audio/video recordings of interviews, correspondence with key informants, or other items that show the steps and rationale for the project. Establishing which methods will be used should be done early in the process and with transparency as the guiding principle, as opposed to reproducibility or replication, which may the goal of an audit trail or research protocol in the quantitative sciences.

Power, positionality, and reflexivity in qualitative research

Among the philosophical assumptions underlying any qualitative enterprise is that the participant is the expert and the researcher must subordinate themselves. Astute qualitative researchers take note of power dynamics through a reflexive process of positioning themselves in the research. The concepts of positionality and reflexivity thus form a "qualitative imperative" ([Boswell, 2021b](#), p. 13)

in social research. In addition to the ‘usual suspects’ of race, class, and gender, one’s research is also subject to both additive and subtractive properties of one’s religious upbringing and activities; military or veteran status; housing, mobility, or incarceration circumstances; caste or tribal affiliation; and numerous manifestations of privilege and birthright. Charmaz (2014) moreover argues that, “Data are never entirely raw. Recording data alone confers interpretations on them because we frame these data through our use of language and understandings about the world” (p. 54). Being reflective about uses of language is an excellent starting point for the practice of reflexive qualitative research.

Reflexivity is a necessary component of the qualitative research process, one that provides “heightened awareness of the self in the process of knowledge creation, and a clarification of how one’s beliefs have been socially constructed” (Grbich, 2013, p. 113). Defined as “researching the self, researching the self in relation to others, engaged reflection and representation, and shifting from the self to system” (Milner, 2007, p. 388), reflexivity in the design and conduct of qualitative research additionally entails scrutinizing one’s positionality as a researcher. **Positionality** is “thinking about the ways in which our social positions shape not only our interactions in the field but also what we see and hear” (Reyes, 2018, p. 212). Disclosures of a researcher’s position relative to participants, data, and the research process are a needed ingredient in strong qualitative studies. These are necessary inclusions because qualitative research “locates the observer in the world” (Strauss and Corbin, 1994, p. 3). Without positionality and reflexivity, research is structured around “inquirer-oriented power” (Cannella and Lincoln, 2011, p. 82). Reflexivity and positionality are therefore paramount in qualitative research, and omitting a disclosure of investigators’ personal contexts is contrary to many best practices within social research.

Summary of Part I

Part I of this chapter has outlined some general philosophical concepts that undergird qualitative approaches to research, irrespective of which theoretical framework(s) one might choose for a research project. In the following sections, the basics of ontology and epistemology will be shown to configure various grand theories that have been instrumental in proliferating the qualitative applications that will be described in the third part of the chapter.

Part II. Theory and theories in qualitative research

Introduction to Part II

There exist broad theoretical and philosophical foundations to qualitative research generally, as well as narrower theoretical frameworks that led to the formation of specific research traditions. This chapter focuses on the broad, macro-level theories, with selected examples of lower-level theories integrated to exemplify contemporary qualitative applications. For instance, many qualitative projects could employ feminism as an overarching theoretical foundation and the project might also use theories within a discipline, such as assessment theories within the field of education or patient-compliance theories within the health sciences.

A **theory** is any articulated way of explaining observed reality—one that usually proposes a relationship between two or more concepts, entities, or sets of conditions. Theories that gain a lot of publicity, whether because they are universally accepted or highly controversial, might be known to a great segment of the general public (e.g., the theory of natural selection) whereas other theories may only be known to specialists in particular fields within a discipline (e.g., theories of how best to teach world languages to adult learners). Throughout this chapter, the emphasis is on ‘grand theories’ or formal, macro-level theories that propose large-scale and wide-sweeping social implications of the status quo.

Historical roots of grand theories

The history of qualitative research is one lens through which to peruse the trajectory of disciplinary communities and divisions, and of conceptions of research from the Enlightenment through the new millennium. Some of the major changes that have contributed to the current state of qualitative research include macro-theoretical assumptions guiding a study; the race, gender, and ethnic background of the researchers as well as of the participants; an increased focus on the potential reciprocal benefits for researchers and participants; and the socio-historic and geopolitical contexts in which research is conceived, funded, and undertaken. These forces continue to sculpt research methodologists and the students to whom they impart their methodologies in a brave new world in which data objects can be tweets, interviews can be conducted remotely, and all manner of artifacts can be crowdsourced in an instant. The *zeitgeist* or ‘spirit of the times’ hews all academic trends to some extent, insofar as it renders certain topics fundable or unfundable, alluringly polemic, or exceedingly popular when a given topic or methodology garners ample airtime at conferences and in themed publications.

Among the major players whose scholarship influenced the early formulations of qualitative social research are Franz Boas, Bronislaw Malinowski, Ernest Burgess, Robert Park, Clifford Geertz, and Margaret Mead. The academic climate in the 1850–1900s in particular was a lightning rod for the burgeoning research approaches that characterize qualitative inquiry today, as influenced by the writings of Weber, Dilthey, Simmel, Husserl, Marx and other timeless icons of the late 19th and early 20th centuries. Just as the *zeitgeist* had an influence on qualitative inquiry over the last century and a half, the *ortgeist* or ‘spirit of the place’ was also of import. In the United States, new directions in **methodology** took researchers from ethnographic field studies in distant locales to research at home in urban and rural settings, where they discovered more and more about the American way of life and the people living it.

Crime (and criminal justice) as a focus of study saw its heyday as qualitative research blossomed in Chicago and other urban centers, while studies of race and poverty knew no limits—rural or urban. Migration trends in the early twentieth century aided social scientists in crafting innovative research questions about integration, segregation, and assimilation in U.S. neighborhoods, in addition to casting new light on the intricacies of public spaces as more and different cultures intermixed therein. Education research moved these questions into the schoolhouse, with more studies focusing on newcomer students and their immigrant families.

The Chicago School of Sociology, together with John Dewey's pragmatic and experiential focus in education, set the stage for deeper examination of individuals' lived experiences as the center of inquiry. The school of thought known as **Symbolic Interactionism** (Mead and Schubert, 1934; Blumer, 1969, 1980) adapted ethnographic methods to "explain why both actors and processes are as they are" (Vidich and Lyman, 2000, p. 38). This focus on the 'actor' highlighted the individual psyche as a worthwhile avenue for qualitative exploration. Symbolic Interactionists contended that one's social experience is mediated by personal and social interpretations of language and other symbols, leading to a watershed for methodologies that prioritized "the meaning people give to their experience" (Bogdan and Biklen, 2007, p. 27). Allowing for subjective and interpretive definitions of reality proved to be the ontological bell that could not be unrung: interpretivist paradigms led to the growth of an experience-centered methodology known as phenomenology.

Throughout this era, thick description and detailed documentation of human behavior were the order of the day in qualitative research. Ethnographers in both sociology and anthropology took pains to analyze multiple sources of data including interviews, maps, audio samples, photography, and meticulous biographical and kinship data—thereby establishing lineage, and linking habits with heritage. Completeness of data and compelling detail became standard as more and more populations under examination were seen to be novel, neglected, or otherwise warranting intensive study. During this period, women were beneficiaries of the propagation of new and exciting pathways in qualitative research—both as practitioners of the research process and as groups/individuals newly represented in qualitative studies. Feminist research, among other major paradigms, is taken up in the following sections.

Major taxonomies of qualitative research

Some theoretical perspectives have been sufficiently developed to have birthed their own methodologies, research communities, journals, conferences, and social movements. These high-level frameworks can be referred to as **paradigms**. A paradigm is a "unitary package of beliefs about science and scientific knowledge" (Crotty, 1998, pp. 34–35). Students new to qualitative research could also think of a paradigm as an overarching worldview that guides research processes and incorporates a researcher's ontology, epistemology, axiology, and methodology. The postmodern paradigm, for example, entails particular beliefs about the nature of reality, what counts as evidence or knowledge, what principles are valued in research and in society, as well as ways to go about studying social phenomena.

Authors of popular works on qualitative inquiry delineate their taxonomies of research paradigms in many different ways. Merriam and Tisdell (2016) note that, "there is almost no consistency across writers in how this aspect of qualitative research is discussed" (p. 8). For example, Neuman (2011) lists three approaches to social science (positivist, interpretive, and critical social science), each with its own set of philosophical assumptions and principles as well as its own stance on how to do research. He includes feminist and postmodern research as separate categories. Merriam and Tisdell (2016) organize this material into four philosophical traditions (positivist, interpretive, critical, and poststructural/postmodern), while Hatch (2002) compares five research paradigms (positivist, post-positivist, constructivist, critical/feminist, and poststructuralist). Lincoln et al. (2018)—in what can be viewed as the seminal work on this topic—review five (positivism, post-positivism, critical theory, constructivism, and participatory).

Bogdan and Biklen (2007) discuss five sets of theoretical underpinnings of qualitative research (positivism, phenomenology, symbolic interaction, ethnomethodology, contemporary trends), while Creswell and Poth (2018) divide their text into philosophical assumptions (ontology, epistemology, axiology, methodology) and interpretive frameworks (post-positivism, social constructivism, transformative frameworks, postmodern perspectives, pragmatism, feminist theories, critical theory and critical race theory, queer theory, and disability theory) in order to facilitate the reader's understanding of qualitative inquiry. Crotty (1998) presents positivism, post-positivism, constructionism, interpretivism, critical inquiry, feminism, and postmodernism as the major paradigms. Despite considerable variation, all of these scholars argue for the importance of understanding paradigmatic tenets of the research enterprise.

Positivism—the paradigmatic view that a singular, objective reality exists and can be accurately measured and observed—is the oldest of these philosophical traditions with its origins in the work of Hume, Mill, Comte, and Durkheim in the 18th and 19th centuries, and that of sociologists such as Robert Merton and Talcott Parsons in the twentieth (see especially Erickson, 2018; Neuman, 2011). Comte (1858) is credited for coining the term "sociology" to advocate for the scientific study of social behavior (borrowed from lab sciences) that came home to roost in the iconic *The Rules of Sociological Method* (Durkheim, 1895), which stands as the first truly empirical and objective study of social phenomena.

Qualitative research after positivism

In contrast to the well-worn objectivist grooves in turn-of-the-century social sciences, many qualitative researchers beginning in the early twentieth century began to question positivism, to the point of using qualitative research as a response to what was absent

from laboratory settings: the **emic**, or insider's expert knowledge and perspective (Merriam and Tisdell, 2016, p. 16). An excellent example of this is Edmund Husserl, a mathematician, who desired a deeper understanding of shared meaning through qualitative methods than that afforded by quantitative designs. This swing away from objectivist thinking toward abstraction created openings within qualitative research for original, post-positivist epistemological frameworks from subjectivism and interpretivism to constructivism, postmodernism, and critical paradigms that scrutinize the power dynamics underlying all social inquiry (Crotty, 1998; Neuman, 2011).

Many contemporary scholars lean more toward a **post-positivist** worldview that, unlike positivism, assumes there exists a knowable, objective, patterned, and stable reality, and which avers that social scientists can only approximate an objective reality through structured and systematic approaches that mirror those historically considered successful in the natural sciences. Importantly, the so-called 'qualitative revolution' in the social sciences, beginning in the 1960s, ran parallel to a 'quantitative revolution' in anthropology wherein many cultural anthropologists adopted quantitative empiricism in fields such as Human Behavioral Ecology to lend what they perceived as more scientific credibility to the study of human behavior (Chagnon and Irons, 1979). Post-positivist worldviews have also been adopted by many qualitative scholars who advocate rigorous and systematic methods in their research and often favor the use of computer assisted qualitative data analysis software and the counting of codes in their analyses.

In post-positivist qualitative research, many projects are subtly or not so subtly influenced by macro-level theories or 'grand theories' that arose in response to positivism and were enhanced by the variation in both where and when they developed, and by whom. Critical theory, postmodern theory, and feminist theories all bear the imprint of the particular political, class, race, and gender dynamics of the eras in which they came into full use in social research. Critical theory or critical social science is a term for approaches that disrupt the status quo by empowering historically oppressed and marginalized groups through research, and achieve a more democratic and equitable society where all individuals can realize their full human potential. Origins of critical theory are credited to Marx, Freud, Fromm, Adorno, and Marcuse, and more contemporary proponents such as Habermas, Freire, Bourdieu, and Tuhiwai Smith (Neuman, 2011).

Feminism can be located within the main framework of critical theory and, similar to some of the other philosophical orientations discussed above, it critically questions masculinist research that directed early scholarship in the study of social behavior. Scholars in the feminist tradition see positivism and its notions of objectivity, logic, rationality, control, claims of value-neutrality, and individual competition as representative of a male point of view that obstructs and underplays the importance of accommodation, interconnectedness, trust, and mutual obligation in the social activities that bevel human interaction (Creswell and Poth, 2018; Neuman, 2011). Feminist scholars pose research questions that expose power relationships, social positioning, and institutional sexism to help transform society and achieve equitable conditions for all. Feminist researchers often employ action-oriented research methods that build solidarity with participants and that are designed to facilitate personal and societal change. Qualitative scholars in the feminist tradition include Margaret Mead, Kimberlé Crenshaw, Patricia Hill Collins, Mary Field Belenky, Carol Gilligan, and Sarah Ahmed, among many others.

Postmodernism in qualitative research is closely tied to the larger postmodern movement across philosophy, the arts, music, and literature, and it shares some overlapping principles with critical theory and feminism. These include, for example, the use of language as a tool of repression of historically marginalized groups, and the rejection of more traditional approaches to the study of social behavior that is viewed as male-dominated, Eurocentric and biased in helping institutionalize and sustain extant power imbalances. In this vein, postmodernists have viewed traditional explanations as forms of critical fiction or myth in that they were so heavily biased by the authors of ethnographic reports that one needs to deconstruct these texts for layered meanings and reject the notion of a single, objective truth (Creswell and Poth, 2018; Neuman, 2011). To them, multiple truths exist. Postmodernists question the grand narratives put forth in those reports and the objective portrayal of the 'other' as historically seen through a White, masculinist, Western lens.

Interrogating the limited perspectives of European research methodologies in the twentieth century qualitative research boom has led to further critique of the preponderance of social science findings that are based solely on samples assumed to be Western, educated, industrialized, rich, and democratic—or "W.E.I.R.D." as a shorthand (Henrich, 2020; Henrich et al., 2010a,b). Breaking the positivist mindset open enables other sets of values to manifest themselves in qualitative inquiry. The third part of this chapter will take up how values guide the research process.

Summary of Part II

The above sections have outlined how paradigms and specific theories originated and how they continue to usher qualitative inquiry in emancipatory directions, to a greater or lesser extent, depending on one's theoretical inclinations and choices. Major qualitative research paradigms such as feminism weave together particular ontologies and epistemologies, often in reaction to previous paradigms' shortcomings. In the following section on research applications, the role of values—axiology—will be in the spotlight, illuminating how values guide each step of the research process.

Part III. Applying theory and philosophy in qualitative research

Methodological sub-approaches are not born into a vacuum; rather, they are forged in the historical and political contexts of a particular time and place, in response to what has come before and challenges thereto. Historical forces drive which research gets funded,

approved, and ultimately completed and published. Imbued throughout all of these decisions are values—personal, institutional, communal, cultural, and political. The study of values in a philosophy or research context is called **axiology** and—together with ontology and epistemology, as outlined above—axiological drivers of research are integral to one’s understanding of contemporary qualitative applications. Consider, for instance, the value of having one’s research make a positive impact in the world; this is not a foregone conclusion for all qualitative researchers. In fact, some would caution against research as advocacy while others wholeheartedly embrace justice-oriented outcomes as a primary aim of their projects.

While opinions differ on whether qualitative researchers should act as advocates for the communities they conduct research alongside, many believe that qualitative research should strive for dignity, respect, and a generous empathy for all individuals participating in the research process. These values underly qualitative inquiry and are evident in the specific theories, methodologies, and methods chosen by researchers. Whereas a quantitative experiment may be “reductive” of human experience (Richards and Morse, 2012), qualitative approaches view human lives as each being situated in diverse particularities. For this reason, qualitative applications require a thorough and comprehensive commitment on the part of the researcher to truly understand and honor participants, to authentically contemplate the implications of the research, and to mitigate the possible harms—literal or representational—of any study being conducted. Axiology, therefore, can be detected at the levels of theory, methodology, and methods, as explained in the following sub-sections.

Values as manifest in theoretical frameworks

As far back as the sociological writings of Du Bois (1898, 1935, 1897), qualitative inquiry has played a crucial role in conveying the lived realities of African Americans and other systemically oppressed or subjugated communities. Bodies of work leveraging such critical epistemologies include general feminist approaches and their subdomains such as Black feminist thought (Berry, 2010; Dillard, 2000), Chicana feminist epistemologies (Anzaldúa, 1987, 2009; Delgado Bernal, 2002), and other criticalities that question and dismantle colonialist and normative perspectives in education and in the social sciences writ large (Delgado and Stefancic, 2017; Patel, 2015; Tuck and Yang, 2012). While space does not permit a thorough analysis of the values of every theory used in qualitative applications, students and novice researchers should keep in mind that being able to articulate one’s values as a researcher and how these inform the choice of a theoretical framework is prerequisite to selecting a methodological sub-approach and research design.

Axiological foundations of specific qualitative methodologies

Increasingly, qualitative research is seen as a venue for amplifying and uplifting individuals, communities, and perspectives that have historically been devalued, dismissed, distorted, or silenced in a given population or culture. Owing to the emic imperative in qualitative research, and embracing the “centrality of experiential knowledge” that derives from many critical race theoretical applications (Pérez Huber, 2009; Solórzano and Yosso, 2016), qualitative inquiry is uniquely poised to elevate scholarship that counters epistemological racism and shortcomings of literature that focus only on the Global North and its limited viewpoints (Kubota, 2020; Scheurich and Young, 1997). From literature reviews and citation practices, to data collection methods, to suggestions for future studies, qualitative research increasingly embodies values of pluralism and antiracism. Arguably, credit for the development of these values in the history of social research goes to the methodology known as Ethnography, explored next.

Ethnography

Ethnography is the study of a culture-sharing group or some aspect of a culture-sharing group and, like some of the other qualitative approaches outlined below, it represents both a process and a product of the research (*an* ethnography). There are currently many forms of Ethnography practiced by qualitative researchers including critical, feminist, autoethnography, life history, ethnographic case study, and ethnographic grounded theory (see *Grounded Theory*, this volume; see also Creswell and Guetterman, 2019). Educational anthropology focusing on the use of ethnographic methods to study education topics emerged in the 1950s, led by George and Louise Spindler, Jules Henry and others, and has grown in popularity over time, having been applied in many and varied educational settings (Creswell and Guetterman, 2019; Erickson, 2018) and foregrounding participant viewpoints.

Field researchers often distinguish between emic perspectives, representing those of the participants, and etic views espoused by the researchers themselves (see Lévi-Strauss (1973) for a discursive history of these two terms). Most ethnographic research allows for a blend of these vantage points. Looking at the history of ethnographic fieldwork, one witnesses a sea change from more etically-driven approaches to emically-based accounts as fieldworkers have underscored the importance of more equitable partnerships and realization of potential benefits for participants. Accordingly, many contemporary ethnographers value transferring the authority from the researcher to the participants—and to the communities they represent—in order to distance themselves from the colonial stigma that has haunted previous ethnographers.

Phenomenology

German philosopher Wilhelm Dilthey laid the foundation for interpretivist paradigms by introducing the notion of *Verstehen* (‘understanding’) to recast reality as being composed, at minimum, of “natural reality and social reality” (Crotty, 1998, p. 67; see also Neuman, 2011). The German philosophical tradition incubated this idea throughout the early 1900s, bringing forth what would later become phenomenological methodology. In the 1960s and 70s, Phenomenology gained popularity, shepherded

by Edmund Husserl—who favored a descriptive or *transcendental* approach—and Martin Heidegger who advanced an interpretive or *hermeneutic* approach. For both of them, the essence of a person's experience was valued as the object of study, shifting research foci from the external and seen toward the unseen and ineffable elements of human existence. Similarly, Mead and Blumer (see Blumer, 1980) promoted Symbolic Interactionism that rested on the idea that people construct reality through the use of symbols, meaning-making, action, and interaction. While interpretivist thinking was inspiring new phenomenological methods and methodologists, a divergent sub-approach that privileges data over interpretation was arriving on the qualitative scene.

Grounded theory

As new targets of focus flourished in qualitative research, so did ways of using the research process to grow or refine current theories across the disciplines. The development of Grounded Theory methodology is one such advance. Grounded Theory values systematic and iterative methods that guide researchers to better understand a social or social-psychological process via a theoretical sample that then undergoes *constant comparative* analysis (Glaser, 1965) until thematic *saturation* is achieved (Hood, 2007, p. 154). Evident in this methodological sub-approach, and at times contested, is the value of collecting a substantial amount of data—whether that be in the number of interviews conducted (Guest et al., 2006), the sampling strategy (Draucker et al., 2007), or the richness or “information power” of the data set (Malterud et al., 2016). Readers can imagine without difficulty that some qualitatively-inclined researchers may take issue with Grounded Theory's emphasis on *quantity* as a valuable dimension of data composition.

Data selection procedures within a Grounded Theory approach signified a departure from the way sites or data sets were chosen for the core ethnographies. Data for the former are chosen based on their potential for grounding heretofore unknown or underdeveloped theory, whereas the latter (ethnographic) data were prized for giving holistic insight into particular groups of people and communities. Hood (2007) notes that, “This focus on emerging theory and theory driven data collection is very different from data collection in conventional ethnography which strives toward thick description of all that can be observed in a given setting regardless of theoretical relevance” (p. 155). Whereas ethnographic fieldwork is characterized by prolonged engagement with a community, some grounded theorists hold as their primary methodological value a prolonged engagement with the data.

We see here that the thick description once honed so carefully by the Chicago School of Sociology, in an effort to position qualitative research as equally ‘rigorous’ to the quantitative studies dominating other scientific fields at the time, came to be of lesser importance during the late 1960s and early 1970s when Grounded Theory was enjoying its halcyon days. That the hallmarks of early qualitative research could move aside in favor of Grounded Theory's systematic approach arguably demonstrates that qualitative research was undergoing a renaissance of sorts—the thick description of the 1920s and 30s' Chicago ethnographers was no longer necessary to evince the rigor of the qualitative approach.

Additional qualitative sub-approaches as values-driven

All sub-approaches within qualitative research showcase values to some extent in their applications. Narrative Inquiry focuses on the participant's personal knowledge as a source of rich data; however, the outcome of the study is seen as a co-creation of both researcher and participant. Some of the philosophical assumptions that define the contours of Narrative Inquiry as a qualitative methodology include temporal experience as fluid, and personal reflection as pivotal, in people's own evolving comprehension of their circumstances. Narrative Inquiry therefore values an alternative, non-realist *teleology*, or the nature of the concept of time.

Along these teleologic lines, a lesser-known qualitative methodology, *Currere*, “foregrounds the relationship between narrative (life history) and practice, and provides opportunities to theorize particular moments in one's educational history, to dialogue with these moments, and examine possibilities for change” (Kanun, 2006, p. 104). From the Latin for ‘to run the course’, this method underscores biography, autobiography, and temporality as lenses through which to view personal experience, and it embodies “the self-conscious conceptualization of the temporal” in a four-step method of reflexive methodology that progresses from *regressive*, to *progressive*, to *analytical*, and finally to *synthetical* inquiry (Pinar, 1994, p. 19). Telicity in *Currere* and Narrative Inquiry is more relativist in nature, whereas Action Research—described next—takes a more realist approach to the concept of time.

Action Research (see *Action and Community-Based Participatory Approaches in Qualitative Research*, this volume) encompasses a wide range of approaches spanning diverse fields such as education, social work, organizational psychology, and other social and health sciences. Broadly defined, it is a systematic, self-reflective, and cyclical process that strives to collaboratively engage researchers and participants toward the goal of generating practical solutions to problems of mutual concern, and spurring positive, long-term change (Babchuk et al., 2021; Brydon-Miller et al., 2011; Creswell and Guetterman, 2019; Grimwood, 2015; Ivankova, 2014). Sub-approaches of Action Research include Participatory Action Research, which values full democratic participation of stakeholders, often involving an explicit focus on political engagement, collaboration, and social justice; and Community-Based Participatory Research, often used in health sciences and aspiring for full community participation in all parts of the research. These forms of Action Research promote equitable partnerships among stakeholders (*i.e.*, researchers, organizational representatives, and members of the community) in all phases of the research process including selecting a research question and the design, implementation, evaluation, and dissemination of the research itself (Israel et al., 2008; Wallerstein and Duran, 2017).

Just as specific methodologies are the product of the special combinations of ontology, epistemology, and axiology that a research community supports, so too are the quotidian practices and procedures that make up a research project start to finish. In the following sections, the values manifest in choosing methods such as member checking, memoing, and more are discussed as they relate to philosophical assumptions about research, researchers, and participants.

Operational values in specific methods and procedures

The specific **methods** employed in qualitative research ought to be deliberately chosen for their appropriateness to the overall design, and for their ability to answer the research question(s) within the timeline and other constraints established. Whatever combination of sampling, data collection, analysis, and write-up methods qualitative researchers choose, project leaders should be able to rationalize why and how each design decision was made. Values are operating beneath the surface of each qualitative application, whether acknowledged or not. The following sub-sections attend to specific procedures in the research process, noting what each one says about values in qualitative inquiry.

Sampling

Although qualitative findings are not intended to be generalized from a sample to a population, thoughtful and rationalized sampling in a qualitative study (see *Qualitative Sampling and Qualitative Data*, this volume) is an opportunity to add rigor and quality, and to enhance the possible application of a study's conclusions. In some sub-approaches, such as Grounded Theory, sampling is an integral part of the data collection and analysis strategy throughout the process. In focus group methodology (see *Focus Groups*, this volume), the make-up of the sample can make all the difference in whether rich data are collected or not. Many qualitative studies rely on purposeful sampling of individuals or communities who possess intimate knowledge of the subject matter. As such, sampling in qualitative research is philosophically aligned with the belief that people's expertise with ordinary facets of their lives is the reason for their selection as participants. The ways of defining the characteristics of a purposeful sample—as well as the number of people in that sample—are contested matters that vary across and within particular research designs.

Interviews

Whereas many qualitative researchers will instinctively lean toward interviews as the primary means of data collection, this choice should not be made unthinkingly, and it is not without alternatives. Interviewing is a common, popular, and powerful means of gathering data from human participants. Infused with the emic lens resident in all qualitative approaches, interviews showcase individuals' perspectives in their own words. However, Kvale (1994) and others have questioned interviewing as a go-to method, arguing that a theoretical or scientific basis for conducting interviews is generally lacking in most research paradigms. Interviews as the principal form of data collection have also been rightly accused of an ableist bias (Kerschbaum and Price, 2017), depending as they do on eye contact, physical or remote proximity and, in most cases, synchronous, spoken language intelligible to both interviewer and interviewee.

Participant observation

Many qualitative studies, especially those using ethnographic methodology, rely in part on participant observation as one data collection method. This means that researchers immerse themselves in the activity, locale, or experience being studied and that they take part as authentically as possible in order to better understand the community they are profiling. Proximity, immersion, detail, reflection, and personal humility while embedding oneself in the study area are highly valued in this method. Although researchers must be judicious in drawing conclusions based on their direct experience of the phenomenon or community under study, the real-time simulation of a cultural phenomenon allows the researcher to gain insights that may not be otherwise available. To balance their personally drawn observations with the views of participants, and to show transparency in the research process, many qualitative researchers include a member checking procedure, as described below.

Member checking

One of the ways qualitative researchers enact values of rigor and transparency is to commit to **member checking** or similar forms of respondent validation, especially when findings from participant interviews are the sole means of data collection. There are numerous and divergent viewpoints on member checking, with some methodologists describing the issue as a “chaos of considerations” (Boswell and Perez, 2021). These include methodological, epistemological, and population- or topic-specific concerns. Member checking also reveals ethical issues such as determining whose interests are served by conducting member checking, and how one might proceed when the interests of the participant, the researcher, and the academic institution sponsoring the research appear to conflict. Some have also questioned whether member checking can cause harm to participants (see especially Hallett, 2013). Thus, one's philosophical assumptions about the nature of truth and the implications of the research situation itself greatly shape research dynamics throughout the process.

Memo-writing and bracketing

There are additional ways that a researcher can apply the values of transparency and humility by acknowledging the limits of their own perspective, although the researcher's private reflections are also highly valued in many methods and methodologies. **Bracketing** or *epoché*, from the Greek for ‘suspension of judgment’, is an ancient Stoic practice requiring the researcher to become aware of—and hold in abeyance—their personal views and experiences related to the subject of inquiry. Many qualitative researchers similarly rely on margin notes and **memos** to document their thoughts as they go, and to brainstorm possible limitations in their approach to the research. Although writing research memos is at times a perfunctory task, this method is grounded in a number of axiological dimensions of naturalistic inquiry. Among them are the need for the researcher to document insights, musings, and possible biases. This reflective and reflexive process manifests the qualitative belief in the researcher as the main instrument

of inquiry, as well as the qualitative imperative for one to consider how one's own social location influences the project. Memos add methodological rigor to the research process and they form part of the audit trail used to assess the researcher and the findings.

Importing qualitative sensibilities into mixed methods research

The philosophical underpinnings of qualitative research have bearing on how qualitative strands are integrated within mixed methods and multimethod designs. Mixed methods practitioners must value numbers, stories, and teamwork in order to transcend the limitations of a single methodology. As argued by Johnson and Walsh (2019), Mixed Methods Research (MMR) rests on the "collection and integration of qualitative data, logics, and philosophies" (p. 521). Because MMR is a "team sport" (Curry et al., 2012) philosophical tension, if not outright conflict, is to be expected. However, the tensions that inhere in mixing qualitative and quantitative traditions can be productive venues for researchers to create a whole that is greater than the sum of its parts. This aligns with the basic methodological rationale of MMR, wherein both the design elements and their execution are undertaken in such a way as to capitalize on the assets of both methodologies while "neutralizing the weaknesses" of each approach (Creswell and Plano Clark, 2018, p. 546).

As a developing field, MMR serves as a role model for articulating whether and why signature qualitative elements should be addressed, including memo-writing, member checking, positionality, and reflexivity, but these qualitative components are not included in MMR manuscripts as regularly as they are in qualitative studies (Boswell, 2021a). Because MMR is often practiced in multidisciplinary teams, "methodological camps" (Curry et al., 2012, p. 10) can inhibit and ultimately disrupt inquiry. Conflicting philosophical assumptions could surface even under the best of circumstances. Due to the breadth of disciplines and philosophies practicing mixed methods research, these designs invite questions about researchers' biases and other backgrounding assumptions, in much the same way that qualitative designs invite reflexivity and disclosures about researchers' own backgrounds and limitations. Historically, some have argued that mixed designs owe their legacy to experimental approaches and "take qualitative methods out of their natural home" (Denzin and Lincoln, 2018, p. 277). For the sake of robust collaboration however, and to ensure the care and feeding of the *dialectical pluralism* at the heart of mixed paradigms (Greene, 2015; Johnson, 2017), mixed methodologists should encourage their diverse research traditions to embrace, and augment, their combined strengths. A qualitative ethos built into a mixed design not only supports a particular project, but can help non-qualitative researchers on an MMR team understand the humanist values at the heart of naturalistic inquiry.

Summary of Part III

A researcher's philosophical assumptions, theories, and values are on display in any qualitative application. The choice of a particular theoretical framework, qualitative design, and the step-by-step methods and procedures selected enact the ontological, epistemological, and axiological stances of the person or people responsible for conducting a qualitative or mixed methods project.

Coda: future directions in qualitative research

Where is qualitative research headed in the pandemic-era, politically polarized 21st century? Current trends presage innovative qualitative and multi-method, collaborative studies suffused with decolonial, postmodern, womanist and post-qualitative works that upend outdated methodologies and supplant them with more participatory methods, social justice themes, and emancipatory outcomes. Approaches such as Black feminist thought and Chicana/o epistemologies overturn longstanding and unexamined Eurocentric theories. In the next generation of qualitative inquiry, methodologists must navigate the antiracist turn in social research, as well as learning to wed multiple ontological and epistemological stances harnessed in service of currently unimagined prosocial aims.

At the same time, there is pushback from segments of academia and public policy that consider whole fields—such as queer studies (see *Queer Theory and Qualitative Research*, this volume), discourse analysis, or critical race theory—to be leftist 'fringe' pursuits plagued by shoddy methods and intellectual navel-gazing. The Sokal Squared Hoax of 2018 (Emba, 2018; Kafka, 2018; Melchior, 2018) shone a light on insular academic communities, which some feel have a penchant for so-called *grievance studies* that shallowly (in the view of some 'anti-woke' critics such as the founders of the new University of Austin in the state of Texas, USA) make all scholarship about dismantling patriarchies. Geertz (2012) referred to these as the 'johnny-come-lately' disciplines—areas such as gender studies, and ethnic studies that comprise the most important subjects on college campuses, as well as the most divisive. Unfortunately, this has inserted an imaginary wedge between the pursuits of rigorous research and justice-oriented social movements.

Currently, in the United States, entrenched and vehement political divisions are accelerating the closure, discrediting, or censoring (Svrluga and Rozsa, 2022) of many collegiate programs and departments dedicated to ethnic studies, gender studies and other newly controversial topics. (Dreger, 2015) telegraphed that this would result in some academicians seeking "regression to the safe" in terms of declaring research priorities (p. 258), but she urges the academy to remember that, "Science and social justice require each other to be healthy, and both are critically important to human freedom" (p. 11). Rather than putting justice and science at odds with one another, qualitative research from this point forward is well positioned to embody their confluence.

The early history of qualitative research in education	14
Differences in orientation among qualitative researchers	17
Conclusion	19
References	19

Over the past century, there has been a huge amount of qualitative research concerned with educational institutions and processes, carried out in many countries. Indeed, education has been a leading field in the development and application of qualitative approaches. In this chapter I will outline the history of this body of work, sketching the range of topics investigated, the diverse forms that qualitative inquiry has taken, and some of the disputes to which these have given rise.¹

Before starting on this, however, it is important to note that rather different histories could be written, depending upon how the words “qualitative” and “education” are interpreted; and, also, according to which countries are covered. I will adopt a relatively broad conception of what counts as qualitative research: as involving the collection of data that are not pre-structured in terms of researcher-defined categories, so that analytic interpretations must be developed during the course of inquiry on the basis of the data. These data may take the form of open-ended fieldnotes, and/or audio- or video-recordings, produced by the researcher via observation or interviews, as well as already available or elicited documentary material (text, audio, and/or visual, still and moving) (Hammersley, 2013a). I will also employ a relatively wide conception of what would count as *educational* research. This can vary in terms of its substantive focus, since education takes place not just in schools and in further and higher education institutions but in other settings too—such as homes, workplaces, and recreational facilities—as well as in networks of various kinds, online as well as offline. The focus may also vary, of course, according to whether it is on teachers, on learning processes, on the motivations and orientations of students, on the role of technologies in facilitating learning or working against it, and so on. As we shall see, what counts as *educational* research has also been a matter of dispute in methodological and theoretical terms, for instance according to whether it simply provides education-relevant knowledge or must be geared *directly* to bringing about educational improvement or change.

While adopting a relatively liberal approach in these terms, I will limit myself to English-language qualitative research, and primarily to that produced in the UK or the US. There is little good justification for these restrictions, my only excuses are the limits to my expertise and the space available.² Even within these limits, given the sheer amount of qualitative research that has been produced, coverage will necessarily be highly selective, designed primarily to give a sense of the range of types of work that emerged at different times; so, what is offered here is certainly not a fully comprehensive account. At the same time, it should provide a reasonably representative picture.

Today, qualitative research in education covers an extremely broad range of topics, takes a very wide variety of forms, and operates on the basis of a diverse range of fundamental assumptions about its purposes, about the nature of the phenomena being investigated, and about how they can best be understood. As we shall see, while the starting point was not some single coherent conception of what constituted qualitative educational inquiry, the proliferation of different approaches and the depth of disagreements has increased sharply over time. In large part, then, this account is a history of that process.

The early history of qualitative research in education

There are, of course, no absolute starting points in history. Qualitative research in education could be traced back at least to the child study movement in the 19th century (see, for example, Preyer and Brown, 1888), including Charles Darwin’s “A biography of an infant”, based on observations of one of his own children (see Hellal and Lorch, 2010). A little later, we could refer to Waller’s (1932) *The Sociology of Teaching*, which drew on his father’s experience as a school superintendent, his own experience teaching in a military academy, as well as case materials provided by teachers (see Everhart, 1989; Willower and Boyd, 1989). However, it was not until the 1950s that we find the beginnings of any sustained tradition of qualitative research in education, and so that is where I will begin.

¹For general accounts of the history of educational research, see de Landsheere (1988) and Lagemann (2000). For accounts of the development of ethnography in the field of education, see Woods (1984) and Hammersley (2018).

²Some sense of developments in other parts of the world can be gained from Milstein and Clemente (2018), Egger and Unterwieser (2018), and Modiba and Stewart (2018). These articles focus specifically on educational ethnography in, respectively, Latin America, Germany and Switzerland, and Africa.

This arose at a time when the dominant kinds of quantitative work in the field of education, and elsewhere, were coming under increasing criticism for failing to meet the rigorous standards they had set themselves and for frequently producing inconsistent or trivial results. Some argued that this stemmed from a fundamental mismatch between the, broadly positivist, philosophy of science that underpinned this work and the very nature of human social life (see, for instance, Bruyn, 1966; Lincoln and Guba, 1985). But also, around this time, there were growing doubts within the philosophy of science about whether positivism offered an accurate picture even of natural science, the most significant example being the revisionist account of the development of scientific knowledge provided by Thomas Kuhn (1962).

In the United States, an important initial development was ethnographic investigations by anthropologists of the relationship between schools and local North American indigenous communities (Spindler, 1955; Dumont and Wax, 1971; Wax et al., 1971; Erickson, 1977; McDermott, 2008).³ This approach was later extended to investigate schooling in other types of local community (Wylie, 1964; Warren, 1967), distinctive forms of religion-based schooling (Peshkin, 1978), the role of key actors within a school (Wolcott, 1984), and educational inequalities within urban communities (Ogbu, 1974). Around the same time, in the field of sociology, drawing on the tradition of the Chicago School, Howard S. Becker (1951, 1952a,b, 1953) carried out a study of school-teachers which significantly informed later work, such as that of Lortie (1975, 2009). Adopting a very different focus, Cicourel and Kitsuse (1963) applied labeling theory and ethnomethodology in studying the role that counsellors played in shaping students' careers in a US school (see also Erickson and Shultz, 1981a). Cicourel followed this up later with a study of the role of language in educational decision-making and testing processes (Cicourel et al., 1974). Outside of anthropology and sociology there were some other pioneering qualitative studies of schools in the US, such as those of Jackson (1968) and Smith and Geoffrey (1968). The first was one of a number of studies that set out to document the reality of life in (American) schools, as against prescriptive accounts. The second was a much more methodologically deliberate study carried out by an observer initially trained in psychology but alienated from some of the main trends within that discipline, collaborating with the practicing teacher whose classroom he was studying. A little later Rist (1973), Cusick (1973, 1983) and Everhart (1983) provided further participant observation studies in schools.

In the UK, the origins of qualitative research are usually traced back to the work of Lacey (1966, 1970), Hargreaves (1967), and Lambart (1976, 1982), which was influenced by both anthropology and sociology, and focused on the differentiation of pupils—in the form of streaming and setting (tracking)—and the consequences of this. And others followed up with similar studies: Ball (1981), Abraham (1995). Later, Hargreaves adopted a rather different approach, applying labeling theory and ethnomethodological ideas in investigating *Deviance in Classrooms* (Hargreaves et al., 1975; Hargreaves, 1976). This reflected a significant shift in orientation within the field in the UK in the early 1970s and there was a considerable expansion in the amount of qualitative research carried out at that time (see Delamont et al., 1993). This included what was labeled “the new sociology of education” (Young, 1971; Sharp and Green, 1976); the development of ethnographic work drawing on symbolic interactionism and social constructionism (Delamont, 1976; Hammersley, 1974, 1976; Stubbs and Delamont, 1976; Woods, 1979; Woods and Hammersley, 1977; Hargreaves and Woods, 1984; Hammersley and Woods, 1984); the work of the Birmingham Centre for Contemporary Cultural Studies, notably Willis's *Learning to Labour* (1977); and the emergence of qualitative approaches in the field of educational evaluation, such as Parlett and Hamilton's (1972, 1977) “illuminative evaluation”, and various forms of “case study” (Stake, 1995; Walker, 1978; MacDonald, 1974).

From the 1970s onwards, in both the US and the UK, there was also work by linguists, sociolinguists, and conversation analysts focused on describing the structure and process of classroom discourse (for instance, Cazden et al., 1972; Sinclair and Coulthard, 1975; Stubbs, 1975, 1976; Payne, 1976; Mehan, 1979; McHoul, 1978; Green and Wallat, 1981, Green 1983), as well as investigating the relationship between language use at home and at school (for instance Brice Heath, 1982, 1983; Philips, 1983). Indeed, around this time there was considerable interplay between linguistics, anthropology, sociolinguistics, and sociology within the field of education. And this is an area where work has continued to develop, for example resulting more recently in the emergence of linguistic ethnography (Rampton, 2006; Maybin, 2006; Copland and Creese, 2015).

While much qualitative research in the 1970s and 80s focused on documenting what was happening in schools and classrooms, there were other sorts of work too. For example, there was some historical investigation of how various school subjects had become established in the curriculum, and how they had changed over time (Goodson and Ball, 1984; Cooper, 1985). Another new development was life history investigations of teachers' careers, showing the effects of external events and personal change over time, and documenting variation in career patterns, notably those related to gender (see Sikes et al., 1985).

From the 1960s onward, there were also some pioneering studies in the field of higher education, notably Becker et al.'s *Boys in White* (1961), a study of a medical school, and *Making the Grade* (1968), an investigation of the experiences and perspectives of undergraduate students in a US university. Meanwhile, Olesen and Whittaker (1968) carried out a similar study of the education of nurses. These investigations stimulated later work, such as Atkinson's (1997) investigation of medical students' experience of clinical training. There was also the pioneering work of Miller and Parlett (1974) on students' orientations toward assessment and examinations. And, in the 1970s, phenomenological approaches to student learning were developed in the field of higher education, under the heading of “phenomenography” (Marton, 1981; Gibbs et al., 1982). There were also a few studies of informal educational processes (see Becker, 1972; Geer, 1972, and other articles in the same issue of the *American Behavioral Scientist*; Lave and Wenger, 1991).

³Long before this some anthropologists had given attention to educational processes, a famous example being Mead's (1928) *Coming of Age in Samoa*. For an account of the history of anthropological work on education, see Mills (2012).

During the remainder of the 20th century and into the 21st, qualitative research expanded hugely, covering many aspects of education. Initially, at least, much of it focused on publicly-funded schooling, and a great deal of it on the secondary level, but even early on there were exceptions. For example, there was the work of Pollard and others on primary schools, some of this taking the form of longitudinal ethnography (see [Berlak and Berlak, 1981](#); [Pollard, 1985, 1996, 1999](#)); see also Andy Hargreaves' (1986) research on middle schools. There were studies of the teaching of particular subjects in primary school, notably science ([Driver, 1983](#); [Driver et al., 1985](#); [Traianou, 2006](#)). There were also some studies of elite private schools ([Delamont, 1973](#); [Howard, 2008](#); [Gaztambide-Fernandez, 2009](#); [Khan, 2011](#)) as well as of vocational training courses ([Bates, 1990](#); [Bates and Riseborough, 1993](#)). In addition, there were a few investigations of teaching and learning outside of school or college settings, for instance Alim's (2011) investigation of Hip Hop practice, [Atkinson et al.'s \(2013\)](#) research on operatic masterclasses, and [Delamont et al.'s \(2017\)](#) account of the teaching and learning of the Brazilian martial art Capoeira.

Perhaps not surprisingly, over time, there was increasing diversity in approach, even within particular disciplinary fields (see, for instance, [Eisenhart's, 2018](#) discussion of the anthropology of education). Key aspects of this were the emergence of critical ethnography ([Anderson, 1989](#); [Carspecken, 1996](#); [Beach and Vigo-Arrazola, 2020](#)), and the development of participatory forms of inquiry, notably in the field of Childhood Studies (see, for instance, [Cuevas-Parra and Tisdall, 2019](#)). Both of these were influenced by the development of feminist ideas about social research methodology (see [Fonow and Cook, 1991](#)), and other theoretical and methodological developments.

A central theme in much work in the sociology of education, and in "critical ethnography", was the role of schooling in reproducing social inequalities. Initially, the focus was on working-class underachievement, and this continued to be a major topic (see, for instance, [Dubberley, 1988](#); [Lareau, 1989, 2003](#); [Weis, 1990, 2004](#); [Weis and Fine, 2000](#)). However, from the 1980s, feminist researchers began to use qualitative methods to investigate the differential treatment of girls and boys in schools, and its effects (see, for example, [Deem, 1980](#); [Delamont, 1980](#)).⁴ This was often conceptualized as curricular and pedagogical discrimination against girls. For example, [Clarricoates \(1980\)](#) explored how primary teachers' gendered expectations shaped their treatment of children in the classroom. Coming from a rather different angle, and drawing on the techniques of sociolinguistics, [French and French \(1984\)](#) investigated the processes by which boys—or, rather, *some* boys—in primary schools gained greater attention from teachers than did girls. There was also exploration of the perspectives and strategies employed by female students to manage the conflicting expectations they faced and achieve their goals (see, for instance, [Measor, 1983](#)), and this led to a considerable amount of work looking at how different versions of femininity were constructed in school contexts and beyond ([Renold, 2001](#)) as well as research on girls' friendships ([Hey, 1997](#); [Gordon et al., 2001](#); [George, 2007](#)) and how they construct gender identities ([Francis, 1998](#)). Later there was also investigation of hegemonic and subordinated forms of masculinity ([Mac an Ghaill, 1994](#); [Renold, 1995](#); [Skelton, 1996, 2001](#); [Kenway et al., 2006](#); [Swain, 2006](#)).⁵ In addition, some attention started to be given to the experiences of Lesbian, Gay, Bisexual, and Transgender students in schools and colleges (see, for instance, [Youdell, 2009](#)).

In the UK, the move away from an almost exclusive focus on social class also led to investigations of the experiences of ethnic minority children in schools. As in the case of feminist research, this was often carried out within the framework of an explicit political orientation, this time an anti-racism which viewed official multiculturalism as an ideological cover for continued prejudice and discrimination, especially of an institutional kind. Much research set out to document discrimination against African Caribbean and South Asian students ([Wright, 1967](#); [Gillborn, 1990](#)). In the US similar studies developed under the heading of Critical Race Studies (see [Lynn and Parker, 2006](#)). There was also investigation of the perspectives and strategies employed by minority ethnic students. For example, [Fuller \(1980\)](#) studied the ways in which a group of African-Caribbean girls adapted to their situation in school, seeking academic success while minimizing their conformity to the demands of teachers. [Mac an Ghaill \(1988\)](#) examined the relations between students from different ethnic groups and teachers in a boys' secondary school and in a sixth form college. In the process, he documented the stereotypes on which teachers operated and the range of adaptations adopted by students, these influenced not just by ethnicity but also by gender. This early work stimulated a whole range of later studies exploring the experiences and perspectives of ethnic minority children in UK schools (see, for example, [Haw, 1998](#); [Bhatti, 1999](#)), as well as at how these influenced subsequent careers ([Saeed, 2021](#)).

During the final decades of the 20th century, and into this century, another major focus for qualitative research in education was the nature and effects of education policies. In a unique investigation [Ball \(1990\)](#) studied the policymaking process by interviewing politicians and officials who had been involved in formulating and implementing key legislation in the UK, and he and others carried out a series of studies of UK policies and their impact (for instance [Gewirtz et al., 1995](#); [Ball et al., 2000](#); [Maguire et al., 2001](#); [Perryman et al., 2011, 2017](#)). A considerable body of work investigated the adaptations of schools and teachers to new policy initiatives and their implications for the nature of teaching and learning ([Woods et al., 1997](#); [Jeffrey and Woods, 1998](#)). Much of this research was concerned with the constraints that various national-level reforms imposed on more progressive forms of education, and the extent to which they worsened existing inequalities. There was also investigation of the impact of school inspections ([Jeffrey and Woods, 1998](#)) and of the effects of stress on teachers generated by rolling waves of new policy initiatives ([Troman and Woods, 2001](#)).

⁴It is also worth mentioning that most previous ethnographic work had been located in secondary schools, whereas feminists gave as much if not more attention to primary schools.

⁵For useful collections illustrating the nature of the work that was done subsequently, see [Walker and Barton \(1983\)](#), [Woods and Hammersley \(1993\)](#), [Skelton and Francis \(2003\)](#).

While I have tried to cover the areas in which qualitative research was most concentrated, there were many other topics investigated, from research on the changing role of technology in schools (see, for examples, [Littleton, 2010](#)) to the character of educational testing (see, for instance, [Cooper and Dunne, 2000](#)). But equally important has been the proliferation of new theoretical and methodological approaches, and this will be my focus in the next section.

Differences in orientation among qualitative researchers

There have been various attempts to conceptualize the increasing diversity in approach among qualitative researchers in education. These operate at different levels, or address it from different angles, and there is also variation according to which country is focused on. At a relatively specific level, [Jacob \(1987\)](#) and [Delamont et al. \(1993\)](#) sketched the various approaches to be found in the United States and the UK, respectively, in the period up to the late 1980s. Subsequently, many other kinds of work differentiated at this relatively specific level have been added, such as Activity Theory ([Roth et al., 2012](#)), Autoethnography ([Goode, 2019](#)), the use of Focus Group Methodology ([Williams and Katz, 2001](#)), visual methods ([Prosser, 2007](#)), and Qualitative Comparative Analysis ([Cooper and Glaesser, 2012](#)).

At a deeper, more philosophical, level, distinctions were often drawn between broad “paradigms”, such as “positivist/post-positivist”, “critical”, and “interpretive” (see [Eisner and Peshkin, 1990](#); [Guba, 1990](#); see also [Hammersley, 1992](#); [Piper and Stronach, 2004](#)). The term “paradigm” was taken from [Kuhn’s \(1962\)](#) work on the history of natural science, but interpreted in a broad way as referring to a set of fundamental assumptions—about the world and how to understand it, as well as about the proper purpose or intended product of research—that could underpin social scientific work. The post-positivist paradigm was portrayed as retaining a commitment to the model of natural science, though interpreting this in a different and more flexible way than positivism. The “critical” approach treats research as properly engaged in challenging the socio-political status quo, focusing on social inequalities, whether in terms of social class, gender, race/ethnicity, sexual orientation, or ability/disability. The interpretivist paradigm places emphasis on the task of understanding the perspectives of the various actors involved in the education process and how these shape their actions. While these broad differences in orientation continue to be relevant today, further differentiation within and beyond them has rendered the field even more complicated. This complexity is nicely illustrated by the fact that influential categories of qualitative inquiry—such as “ethnography”, “action research”, and “discourse analysis”—each contain multiple variants, often differing in fundamental respects.

Not surprisingly given this process of diversification, there have been recurrent disputes among qualitative researchers relating to methodological and theoretical matters. These began in the 1950s within the anthropology of education over the “culture and personality” perspective that was adopted initially in this field. While later work maintained the focus on culture, some of it adopted a more micro-focused approach, and rejected a psychological in favor of a more sociological orientation (see [McDermott, 1977](#); [Erickson and Shultz, 1981b](#); [Garcez, 2008](#)). These moves generated a significant debate with anthropological advocates of holism. They insisted that what happens in particular situations on particular occasions cannot be understood without being located in an understanding of the wider community, the whole society, and perhaps even global processes and relationships (see, for instance, [Lutz, 1981](#)). And, along with this, there were also some who emphasized the need for cross-cultural, comparative analysis. But many insisted that detailed analysis of processes of social interaction is required if these are to be understood, raising questions (implicitly or explicitly) about the validity of claims about macro-level contexts. Over the second half of the 20th century and into the 21st, there has been continuing tension and oscillation between these two emphases.

This issue, frequently conflated with differential weight given to “structure” and “agency”, also arose within the sociology of education in the 1970s and 80s. This reflected the growing influence of Marxism, in the wake of the new sociology of education. Some Marxists treated schools as locked into the reproduction of capitalist societies (see, for instance, [Anyon, 1980, 1981](#)), but many qualitative researchers in the UK, while not denying the pressures on schools to serve this function, emphasized the agency of teachers and students and the significance of processes of social interaction (see [Hammersley, 1980](#)). In addition, they complained that Marxist analyses failed to engage sufficiently with the problems involved in producing and analyzing data about school processes, tending to present just-so stories derived from Marxist theory rather than well-researched accounts ([Hargreaves, 1982](#)). A famous example that stimulated considerable controversy was [Willis’s \(1977\) *Learning to Labor*](#), a study of a small number of working-class boys with an oppositional attitude to school. While Willis stressed the agency of the boys, he portrayed them as exercising that agency in such a way as to condemn themselves to working class jobs, thereby reproducing capitalism (for critical assessments, see [Turner, 1979](#); [Walker, 1985](#); [McGrew, 2011](#)).

Somewhat similar debates took place in the United States, one example being a dispute between [Cusick \(1985\)](#) and [Everhart \(1985\)](#), ([Cusick and Everhart, 1985](#)). Both these authors had produced participant-observation studies of schools, and a journal assigned them to review one another’s books. Cusick complained that in Everhart’s account: “Although students are described and presented in a human and believable manner, administrators and teachers are described only through the eyes of the students and the Marxist perspective. In effect they are presented as mere unwitting tools of capitalist oppression” ([Cusick, 1985:71](#)). Meanwhile, Everhart criticized Cusick’s “overly-rigid adherence to a functionalist approach”, and a failure to “address at all the manner in which [the school] system works within the context of the larger sociopolitical order” ([Everhart, 1985:75](#)).

Another area of dispute was the relationship between research and educational practice. An influential strand of research coming out of the educational evaluation movement promoted various forms of action research ([Hendricks, 2019](#)). As part of this it was often argued that education research must be *educative* in character, in the sense of directly serving the improvement of educational

practice, rather than simply contributing to knowledge about educational processes, institutions, and outcomes. This sparked responses from some qualitative researchers committed to more “academic” forms of research, who questioned the quality of much that came under the heading of educational evaluation and action research (Atkinson and Delamont, 1985) and even whether action research could be a coherent enterprise (Hammersley, 2004). As already noted, though, action research fragmented into a range of competing approaches that were incompatible with one another in significant respects, from those adopting a “critical” orientation, according to which action research could challenge capitalist society, to those who viewed it entirely in terms of the educational development of individual teachers or the solution of practical classroom problems (see Kemmis, 1988).

In the 1980s there were debates sparked by feminism and anti-racism, with criticism directed at mainstream research for neglecting gender and race/ethnicity, and thereby overlooking significant forms of inequity. However, there was also some counter-criticism, with critics arguing that much research guided by feminism or anti-racism was speculative in character, substituting political assumptions for careful and systematic empirical investigation of what happens in schools, and of the complexities involved in the production of inequalities in educational outcomes (see Foster et al., 1996). For example, Foster (1990) challenged the adequacy of some of the work that claimed to document discrimination against ethnic minority students by teachers in UK schools, pointing to serious weaknesses in the evidence on which conclusions were based, and arguing that a bias was operating in the interpretation of this evidence.⁶ Foster’s criticisms of anti-racist research, supported by others (Gomm, 1993; Hammersley and Gomm, 1993; Foster et al., 1996), were met with a counter-charge of “methodological purism”: of using methodological arguments to discredit evidence of discrimination, as a result of unconscious racism (Gillborn and Drew, 1993; Troyna, 1993; Gillborn, 1995). The issues involved here were important ones, but little progress was made toward resolving the disagreement. Indeed, the debate raised questions about whether there was any scope for dialogue between “critical” and analytic approaches; some commentators appeared to remove any possibility of this (see, for instance, Scheurich and Young, 1997), reflecting the growing influence of Critical Race Theory (Taylor et al., 2016; Dixon et al., 2017).

From the 1980s onwards, research on education, as in other fields, was influenced by the range of ideas often given the label “postmodernism” (see Stronach and MacLure, 1997). These amounted to a selective appropriation and interpretation of influential French philosophical thinking from the 1960s and early 70s, particularly the work of Foucault and Derrida. One central theme was the role of various types of institution, including schools, in normalizing behavior by pedagogic or therapeutic means—this often done in the name of scientific expertise. Postmodernism highlighted the rhetoric and functioning of social science in this process, and reinforced a commitment on the part of many researchers to the championing of marginalized groups and their “subjugated forms of knowledge”. As part of this, claims to scientific expertise were attacked, not least through questioning the very possibility of the kind of knowledge science purports to offer, in which facts are presented on the basis of scientifically-controlled observation and analysis of one sort or another. In the firing line here was not just quantitative research but also many forms of qualitative inquiry. Any capacity of language to represent phenomena existing independently of it, or indeed to anchor and preserve meanings in the manner required for this, came to be denied by some educational researchers. The artifactual, if not fictional, character of all accounts of the world was emphasized, with literature and art increasingly treated as the appropriate model rather than science; though the rhetorical value of the latter continued to be recognized. The tension that had always been present within qualitative research between science and art was given a new twist, in fact several twists (see, for example, some of the articles in Reid et al., 2014).

An important effect of postmodernism was to increase the amount of attention given to the role of discourse (MacLure, 2003): official accounts, especially, but also those of informants in interviews, were no longer to be treated as accurate or inaccurate representations of the world but rather investigated for the work that they do in constituting and sustaining particular “truth regimes” within educational institutions and elsewhere—especially ones taken to be unjust. Thus, discourse analysis was often used to serve the same “critical” function as earlier forms of Marxist ideology critique, even though the previously assumed contrast between ideological and objective scientific accounts had been abandoned. Another effect of postmodernism was an exploration of alternative ways of pursuing and presenting the product of educational inquiry, for example the use of poetry, dance, and drama, much of this coming to be included under the heading of “arts-based research” (Bagley and Cancienne, 2002; Atkinson, 2012; Sikes, 2012; Leavy, 2018).

In the 1990s and into the 21st century a major conflict was prompted by the evidence-based practice movement and its promotion of Randomized Controlled Trials (RCTs) and systematic reviews as the “gold standard” source of evidence for educational policymaking and practice. Here, the older debate between quantitative and qualitative approaches was revived, albeit in a somewhat different form. There was growing public criticism of qualitative research in some influential quarters, on the grounds that it lacked scientific validity and that it did not serve educational policymaking and practice effectively (Hargreaves, 1996; see also Hammersley, 1997; Hillage et al., 1998; Tooley and Darby, 1998; National Research Council, 2002, Hammersley 2007). In the United States, a key development was the reauthorization of the Elementary and Secondary Education Act (“No Child Left Behind”) in 2001, which prioritized RCTs as a source of evidence in relation to educational practice. Increasingly, the use of RCTs was institutionalized by government in both the US and the UK (Hammersley, 2013b). Qualitative researchers reacted sharply against what they regarded as a devaluing of their work (see Lather, 2004a,b; Denzin and Giardina, 2006; Torrance, 2011). In the UK, the Economic and Social Research Council’s *Teaching and Learning Research Program* (TLRP), initiated in 2000 and ending in 2011, boosted investment in education research designed to make a practical contribution to educational practice; though quite a lot of this research was

⁶For full references to Foster’s work, and a discussion of the debate, see Hammersley (1995: ch. 4).

qualitative in character. Subsequently, sponsored by the UK Government, the Education Endowment Foundation has funded a considerable amount of research aimed at providing evidence about the effectiveness of various educational strategies and practices, much of this relying on RCTs.

In the wake of attempts to defend qualitative research against the resurgence of positivist ideas, along with a funding emphasis on quantitative method and the rise of the mixed methods movement, some qualitative researchers have raised the prospect of a move to the “post-qualitative” (Lather and St. Pierre, 2013; St. Pierre, 2019). They have pointed out how, to a large extent, the distinction between quantitative and qualitative approaches, and the opposition between positivism and other research philosophies, is founded on the assumption of a fundamental distinction between the physical phenomena that the natural sciences study and human social life. Some recent ideas, often going under the headings of “new materialisms” and “post-humanism”, question the previously assumed ontological basis for that distinction, insisting that positivist assumptions about the nature of physical phenomena do not take account of more recent developments in the natural sciences—for example quantum physics and epigenetics in biology. Involved here is an appeal to vitalist conceptions of matter, with the latter viewed as having agential capabilities that previous approaches to qualitative research had tended to restrict to human beings. There is also a link here to a valorization of indigenous cultural beliefs (Rosiek et al., 2020). In part this amounts to a reaction against the previous emphasis on discourse by qualitative researchers, characteristic of work influenced by post-structuralism and postmodernism, in favor of a focus on material processes. Thus, post-humanism rejects the idea that reality is constituted in and through the discursive or cognitive practices employed by human beings, and especially those of Western intellectuals. There is a focus on the role of technologies and material artifacts, and a recognition of both the ways in which nature (for instance the world’s climate) is being changed by human beings and how human social life is interpenetrated by materialities, with technologies no longer being mere tools but actually doing work that humans previously did, such as EdTech teaching programs, and increasingly reshaping human bodies in various ways from hearing implants to wearable computing and embedded microchips to control behavior. The post-qualitative movement is by no means single-stranded, and at present it is difficult to know what consequences it may have for qualitative research in education. These developments bring us up to the present-day; and, if we were to take the phrase “post-qualitative” literally, to the end of the history of qualitative research.

Conclusion

In this chapter I have outlined some of the history of qualitative inquiry in the field of education, and sought to provide a sense of the range of different areas of work and the proliferation of methodological and theoretical approaches that have developed there. As part of this, I looked at several of the disputes among qualitative researchers that have taken place over the years, these reflecting quite fundamental differences in assumptions about the nature of social and educational phenomena, how these can best be understood, and what the function of research ought to be. It is important to be aware of how current ideas and practices developed, since this will enable us to understand them better. It may also tell us to what extent we are merely treading water, or going round in circles, rather than making progress. Even aside from this, when doing research it is necessary to have a clear sense of the rationale for the kind of work one is doing in the context of the whole range of alternative approaches, their relative strengths and weaknesses, affordances and problems.

A key issue that arises from this history is whether the deep pluralism that now prevails was an inevitable product of the expansion of educational research, and of social inquiry more generally, or whether rather more agreement about fundamental issues could have been, and perhaps still can be, achieved. But there have also been disagreements about whether such pluralism is desirable or undesirable (Hodkinson, 2004; Hammersley, 2005; Lather, 2006). While the tension with quantitative method remains for many qualitative researchers, there is now little agreement among them about theoretical and methodological issues; and, as we saw, some erstwhile qualitative researchers wish to abandon or transcend it to enter a new post-qualitative age. The future is, as always, uncertain, but in facing it we would do well to learn what we can from the past.

For scholars who are not familiar with or have not previously conducted qualitative research, the options available for framing and carrying out a study can seem bewildering. It is important at the outset to define qualitative research. [Creswell and Poth \(2018\)](#) stated that qualitative research:

... begins with assumptions and the use of interpretive/theoretical frameworks that inform the study of research problems addressing the meaning individuals or groups ascribe to a social or human problem. To study this problem, qualitative researchers use an emerging qualitative approach to inquiry, the collection of data in a natural setting sensitive to the people and places under study, and data analysis that is both inductive and deductive and establishes patterns or themes. The final written report or presentation includes the voices of participants, the reflexivity of the researcher, a complex description and interpretation of the problem, and its contribution to the literature or a call for change (p. 43).

Our colleagues, through accompanying chapters in this volume will describe the philosophical underpinnings of qualitative research as well as the history of qualitative research in education. In this chapter however, our purpose is to simplify the choice of methods for scholars by presenting a more easily understandable overview of qualitative research approaches. We choose the term qualitative approaches ([Creswell and Poth, 2018](#)) here to refer to the ways in which the research can be organized or framed, although in the literature other terms appear such as varieties ([Tesch, 1990](#)), categories ([Slife and Williams, 1995](#)), traditions ([Creswell, 1998](#)), methods ([Morse and Richards, 2002](#)), and strategies of inquiry ([Denzin and Lincoln, 2005](#)).

For new qualitative researchers the problem is not that there is not enough information on the approaches available, but that there exists an almost baffling array and volume of literature. Further, within the literature of many approaches is a tangled history of the development, key scholars, and resulting variations of the approaches, which can lead to the confusion and frustration of many beginning researchers. Thus, we have approached writing this chapter from the viewpoint of an academic (first author) who assists students with doctoral research in the field of education and a graduate student (second author) who is currently conducting doctoral research in education. In our discussion of each qualitative approach, we have taken pains to be clear on its definition and characteristic features, to provide a brief background, including key scholars, to describe its evolution and resulting variants of the approach, to discuss its strengths and weaknesses, and to provide examples of studies in education using the approach. Additionally, in the spirit of this international publication we have tried to include studies from around the world representative of the various qualitative approaches as applied in the field of education. For the sake of simplification and due to space constraints, we will discuss the five established qualitative approaches (i.e., case study, phenomenology, grounded theory, narrative inquiry, and ethnography) ([Creswell and Poth, 2018](#)), as well as two additional qualitative approaches (i.e., discourse analysis and participatory action research) more commonly seen in educational research studies. [Table 1](#) provides an overview of the qualitative approaches, key characteristics, and representative studies in this chapter.

Case study

Case study is a popular method of conducting research as evidenced by our recent database query which yielded 465 English language dissertations with “case study” in the title published in the last 5 years. Case studies have been used in a number of disciplines and fields of study including psychology, anthropology, sociology, law, and medicine. A case study is defined as the in-depth study of a case or cases in a real-life, contemporary context or setting ([Yin, 2014](#)). Case studies have historically been used to answer how or why questions ([Yin, 2014](#)). A case, or the object of the study, can be an organization, program, or

Table 1 Overview of qualitative research approaches, key characteristics, and representative studies.

<i>Qualitative research approach</i>	<i>Key characteristics</i>	<i>Representative studies</i>
Case study	A case study is defined as the in-depth study of a case or cases in a real-life, contemporary context or setting (Yin, 2014). Case studies have been used in a number of disciplines and fields of study including psychology, anthropology, sociology, law, and medicine. Case studies have historically been used to answer how or why questions (Yin, 2014).	Single case study: Hoppey and McClesky (2013) Multiple case study: Delmas and Ivankova (2018)
Phenomenology	Phenomenology is a method in which researchers make it their focal point to study human experiences, including the ways people conceptualize their lived, shared experiences (Braun and Clarke, 2013; Sokolowski, 2000). Phenomenology concentrates on the perceptions and communications of people regarding certain events or objects. This approach can be used to analyze individual cases or to develop cases from a small group of research participants (Braun and Clarke, 2013).	Transcendental phenomenology: Moerer-Urdahl and Creswell (2004) Hermeneutic phenomenology: DeGagne and Walters (2010)
Grounded theory	Grounded theory is defined as the discovery of theory from data (Glaser and Strauss, 1967). This approach focuses on a certain development or activity that is unfolding, ideally leading to the researcher's creation of a theory regarding this series of events or process (Creswell and Poth, 2018). Essentially, the theory centers on the researcher's end goal of forming a theoretical frame which sheds light upon a particular phenomenon, or series of events, including how the phenomenon began, grew, and changes (Charmaz, 2014).	Classic grounded theory: Chametzky (2015) Straussian grounded theory: Vassilakaki and Johnson (2015) Constructivist grounded theory: Karpouza and Emvalotis (2019)
Narrative inquiry	Narrative is both a phenomenon and a method (Connelly and Clandinin, 1990). Narrative inquiry, also called narrative research is the study of people's experiences. Narratives or stories are the object of analysis (Caine et al., 2013). The experience can be studied by "listening, observing, living alongside another, writing, and interpreting texts" (Clandinin, 2006, p. 46).	Autobiography: Grace (2006) Biographical study: Stroobants (2005) Life history: Tsui (2007) Oral history: Delaney and Raftery (2020) Testimonio: Cordova and Knecht (2019) Visual narrative inquiry: Sairanen and Kumpulainen (2014) Collaborative autoethnography: Chang et al. (2014) Critical ethnography: Smyth (2016) Institutional ethnography: Lund (2012)
Ethnography	Ethnography is employed when the researcher's goal is to document what actually happens in a natural setting. The data collection typically occurs over a long period of time, and includes a range of data types, with a heavy emphasis on participant observation. Researchers agree that ethnography does not focus on the culture of a group, but rather on the patterns of a group (Wolcott, 2008), or the beliefs, behaviors, language, and interactions of a group which shares the same culture (Creswell and Poth, 2018).	Descriptive discourse analysis: Iverson (2016) Critical discourse analysis Thompson (2002)
Discourse analysis	As a research approach discourse analysis has application across a broad array of fields of study, including communications, anthropology, sociology, and nursing. The two primary types of discourse analysis are descriptive and critical. Descriptive discourse analysis seeks to understand how language influences people and situations. Critical discourse analysis seeks to expose through description and interpretation the ways that social inequalities are constructed, maintained, and legitimized (Mullet, 2018).	Participatory action research: Ditrano and Silverstein (2006), Halliday et al. (2019)
Participatory action research	The term participatory action research (PAR) is considered an umbrella term because it encompasses a range of approaches to participatory action-oriented studies (Kindon et al., 2007). Participatory action research combines elements of community-based research, popular education, and action for social change (Lewin, 1946; Williams and Brydon-Miller, 2004). Brydon-Miller and Maguire state that PAR is "an openly and unapologetically political approach to knowledge creation through and for action" (2009, p. 79). PAR is a collaboration between researchers and participants whereby a problem or issue is investigated with the purpose of finding a solution or seeking improved conditions. Key to PAR is its central feature of democratizing research through a partnership between researchers and participants.	

process (Yin, 2003), instant, event, occasion, or person (Schwandt, 2015). The defining characteristic of a case study is a delimiting of the case (Merriam, 2001). A case is a bounded system. In other words, it is bounded by time and place. Another hallmark of case study is its use of multiple sources of information (Creswell and Poth, 2018) such as interviews, observations, documents, artifacts, and audiovisual material. These multiple sources of information should lead the researcher to the same findings, thus aiding in triangulation and helping to establish the credibility of the research (Yazan, 2015).

There are two types of case designs, case studies and multiple case studies, depending on the number of cases being studied. Case studies may be further classified as exploratory, descriptive, or explanatory (Yin, 2014), or intrinsic or instrumental (Stake, 1995). Exploratory case studies are used as a means to identify the research questions or procedures that will be employed in a future study. Descriptive case studies aim to describe the phenomenon, or case, in its natural context. Explanatory case studies aim to reveal how a condition or situation arose. An intrinsic case study emerges from the need to learn about a particular case, whereas an instrumental case study is employed when one seeks to learn about a larger issue or phenomenon by exploring one case.

Some of the strengths of the case study approach are that it can aid in the discovery of the unexpected and unusual, facilitate an understanding of complex relationships (Hodkinson and Hodkinson, 2001), and provide an in-depth grasp of a case. Weaknesses or challenges inherent in the case study approach include difficulty in identifying the case and determining its delimitations, and the potential for accumulating an unmanageable amount of data.

Yazan (2015) offers a comparative analysis of three case study approaches by leading methodologists which may be useful for scholars considering designing a case study. Examples of two different types of educational case studies are described here as illustrations of single and multiple case studies. Hoppey and McClesky (2013) used a single case study to examine the “role of the principal in supporting school improvement during an era of high-stakes accountability” (p. 247). In this study the lived experience of the principal was the case, bounded by time (one school year) and place (the elementary school in rural Florida). Delmas and Ivan-kova (2018) employed a descriptive, multiple case study in their examination of the academic experiences of three Catholic nuns serving as faculty members at universities in the American South. In their research, the academic experiences of each woman served as a case, and was bounded by time (February 2005–April 2006) and place (the geographic boundaries of the research sites in the South).

Case studies are a popular qualitative research approach in education. Their pervasiveness means that most researchers are likely to be familiar with case studies. The case study approach allows the researcher to develop a deep understanding of the object of study, whether the reason for the research is to learn more about a unique phenomenon or to investigate a specific problem or issue. To learn more about case studies, see the chapter on Case Study Research by R. Stake in this volume.

Phenomenology

Phenomenology is a method in which researchers focus on studying human experiences, including the way people conceptualize their lived, shared experiences (Braun and Clarke, 2013; Sokolowski, 2000). Phenomenology concentrates on the perceptions and communications of people regarding certain events or objects. This approach can be used to analyze individual cases or to develop cases from a small group of research participants (Braun and Clarke, 2013).

Phenomenology's popularity in the US has waxed and waned with initial enthusiasm for the method from scholars in the 1960s and a resurgence of interest from cognitive scientists in the 1990s (Gallagher, 2012). Dall'Alba (2009, p. 7) noted that “as the impact of phenomenology extended beyond philosophy to fields such as sociology, education, anthropology, politics, linguistics, psychology and feminist studies, it has challenged taken-for-granted assumptions and prompted new insights into what it means to live, work, play and learn in our world.”

Braun and Clarke note that while there are a number of types of phenomenology, the method can generally be described as concerned with understanding people's subjective experiences (2013). The two primary types of phenomenology are transcendental (also referred to as empirical or psychological) and hermeneutic. Transcendental phenomenology is built on the philosophical work of Husserl (1931) and applied specifically as a qualitative approach by Moustakas (1994). It is descriptive and focuses on how experiences are structured and organized. This approach “analyzes the essences perceived by consciousness with regard to individual experiences” (Padilla-Diaz, 2015, p. 103). Hermeneutic phenomenology, based on the work of Heidegger (1972) is defined as research centered on personal experiences and requiring interpretations or descriptions of the meanings and significance of phenomena which participants experience (Padilla-Diaz, 2015). This approach requires a historical analysis of the phenomenon and its effects on participants.

An example of a transcendental phenomenology in education is Moerer-Urdahl and Creswell's (2004) study of nine participants in a US college mentoring leadership program which sought to understand the meaning of the mentors' experiences. This study may be especially helpful to researchers planning to undertake a transcendental phenomenology as it describes in detail the process of organizing and analyzing data according to Moustakas's (1994) tradition. While hermeneutic phenomenology is used much more commonly in the health professions, DeGagne and Walters (2010) have applied the approach to a study of the lived experiences of 11 online educators from varying locations in the US. From the study results, the authors proposed recommendations for the improvement of online learning communities. Padilla-Diaz (2015) offers a clear discussion of basic concepts and essential elements of phenomenology for those seeking further guidance to this qualitative research approach.

While phenomenology allows for the in-depth exploration of the meaning of a lived experience or a phenomenon using a small group of participants, there are challenges to this approach. Finding participants who have experienced exactly the same phenomenon may prove difficult. Additionally, the bracketing (also called *epoché*) of the researcher's experiences and assumptions, required in transcendental phenomenology, may be onerous to inexperienced scholars.

Phenomenology is a versatile qualitative approach. It can be employed to explore a single concept or to analyze that concept as it is experienced by a group of people. Phenomenology can assist in discovery of new facets of experiences and phenomena that are so common as to be considered mundane. As Lavery (2003) explained, phenomenology can aid in a re-examination of an experience or phenomenon that may reveal different perspectives, helping to cast them in a new light. For more information about phenomenology, see the chapter on Phenomenology and Education: Researching Pedagogical Experience by N. Friesen in this volume.

Grounded theory

Grounded theory is defined as the discovery of theory from data (Glaser and Strauss, 1967). This approach focuses on a certain development or activity that is unfolding, ideally leading to the researcher's creation of a theory regarding this series of events or process (Creswell and Poth, 2018, p. 83). Essentially, the theory centers on the researcher's end goal of forming a theoretical frame which sheds light upon a particular phenomenon, or series of events, including how the phenomenon began, grew, and changes (Charmaz, 2014). Because of this, grounded theory can lead to the development of a useful theoretical frame which helps to explain an incomplete or disorganized phenomenon (Corbin and Strauss, 2015). Grounded theory's application has grown widely and now appears in numerous areas of study including education, medicine, nursing, psychology, social work, religion, gender studies, and anthropology. Morse (2009) speculates that grounded theory may be the most commonly used qualitative research method.

Two American sociologists, Barney G. Glaser and Anselm L. Strauss, are considered the fathers of grounded theory (Kenny and Fourie, 2014). They purposefully named the method *grounded theory* in order to describe its intent to "ground" theory in empirical research. Conducting a classical grounded theory study involves an iterative process of coding, memoing, sorting, conceptualization, and constant comparison. Over time the approaches that Glaser and Strauss took to grounded theory diverged, resulting in classical grounded theory and Straussian grounded theory. Straussian grounded theory grew out of a collaboration between Strauss and Corbin (1990), and relied on an analytical coding framework designed to systematically infer theory from data (Kenny and Fourie, 2014). A student of Glaser and Strauss, Kathy Charmaz, is associated with a third variant of grounded theory, called constructivist grounded theory (Charmaz 2006, 2014), which highlights the phenomenon under investigation rather than the methods utilized to study it (Charmaz, 2005).

Hussein et al. (2014) state that the strengths of grounded theory include its richness of data, cultivation of creativity, intuitive appeal, capacity for conceptualization, and systematic approach to analyzing data. Alternatively, the authors list weaknesses of the theory as "exhaustive process, potential for methodological errors, reviewing the literature without developing assumptions, multiple approaches to GT, limited generalizability" (p. 3). As a remedy to aid in understanding the multiple approaches, Kenny and Fourie's (2014) article does an admirable job of laying out the history of grounded theory and tracing its development through the three variants of grounded theory. Additionally, Tan's (2010) article may be useful to scholars new to the grounded theory as it attempts to clarify common confusions with the approach through an examination of the author's doctoral study investigating post-secondary students' learning and knowledge sharing as evidenced through blogging.

Following are examples of the three common variants of grounded theory as used to frame research studies. Chametzky (2015) used a classic grounded theory approach to understand the issues of contingent, part-time faculty in US higher education, with a sample of 11 participants. The resulting theory, surviving situational suffering, described how contingent faculty dealt with their primary concern—remaining employed—while simultaneously operating under conditions of lesser appreciation, gratitude, and utilization (Chametzky, 2015). An example of a Straussian grounded theory study can be found in the research of Vassilakaki and Johnson (2015) which used 24 undergraduate and graduate participants from Manchester Metropolitan University in the UK to identify elements of the user experience in information searching on an experimental multilingual information retrieval system. Karpouza and Emvalotis (2019) employed a constructivist grounded theory using 20 teacher educators and 25 graduate students from master's programs in Educational Sciences in Greek universities to explore the teacher-student relationship in graduate education. To learn more about grounded theory, see the chapter on Grounded Theory by W. Babchuk in this volume.

Narrative inquiry

Narrative is both a phenomenon and a method (Connelly and Clandinin, 1990). Narrative inquiry, also called narrative research is the study of people's experiences. Narratives or stories are the object of analysis (Caine et al., 2013). The experience can be studied by "listening, observing, living alongside another, writing, and interpreting texts" (Clandinin, 2006, p. 46). Researchers in the social sciences began using narrative inquiry in the late 1980s. Connelly and Clandinin (1990) first used the approach in education to recount the personal stories of teachers. The types of data used in narrative inquiry, which Clandinin and Connelly (2000) call *field texts* include photographs, field notes, conversation transcripts, and interview transcripts. To the list of potential data sources Savin-Baden and Niekirk (2007) added letter writing, and autobiographical and biographical writing.

Types of narrative inquiry include: autobiography, where the narrative is created by the researcher from their experiences; biographical study, where the researcher reports on the life of a participant; life history, which recounts a participant's entire life; oral history, which is composed of the reflections of one or more participants on events and their causes and effects; testimonio, which is reported in first-person by the participant and urges the reader into acknowledgment of the urgency of addressing social wrongs; and visual narrative inquiry, where images are analyzed alongside text.

Savin-Baden and Nierkerk (2007) have pointed to the ease in getting people to talk and the ease in accumulating data as strengths of the narrative inquiry approach. A counterpoint is that the data can be cumbersome and participants may not report their experiences in a linear or chronological fashion. Additionally, Clandinin and Connelly (2000) caution that power relations between the researcher and participant may pose a challenge to the narrative inquiry approach. Because of its characteristic of research over time, narrative inquiry has been recognized as a particularly effective methodology in the field of medicine where it can be used to tell the stories of individuals with chronic illness (Bleakley, 2005). Narrative inquiry is also noted as being effective in educational leadership to aid individuals in career path exploration and identity formation (Floyd, 2012).

Examples of the six types of narrative inquiry previously described are given here as starting points for scholars who wish to learn more about this research approach. Grace (2006) employed queer autobiography to link the personal to positional practice as an educator and gay man living in Canada. Stroobants (2005) reflected on the stories told by both participants and the researcher as well as the learning processes that they went through during a narrative biographical study of eight women who had participated in adult education initiatives. To explore the processes of teacher identity formation, Tsui (2007) used life history to examine the professional identity of an English as a Foreign Language teacher in the People's Republic of China. Through oral history accounts Delaney and Raftery (2020) provided insight into the ways in which Ireland's Free Education Scheme of 1967 impacted the lives of 16 Catholic sister educators with leadership/management responsibilities. Employing testimonios, Cordova and Knecht (2019) explored the perceptions of three Chicana/o doctoral students in an US educational leadership program regarding the intersection of their gender, race, and ethnicity as it related to their academic advancement and leadership development. Finally, Sairanen and Kumpulainen (2014) used visual narrative inquiry to explore the sense of agency in educational settings for five Finnish children in pre-school and first grade.

The narrative inquiry approach is best used when the researcher wants to explore the life experiences of a person or persons. It is achieved through the participant telling stories about some aspect of their life. The researcher's responsibility is to organize the stories into a meaningful, typically chronological format that represents the participant's experiences. The end result often helps provide insight not only into the participant's life, but also the society, culture, or era in which their experiences occurred. Further information on narrative inquiry can be found in D.J. Clandinin's Narrative Inquiry chapter in this volume.

Ethnography

Like many other qualitative methods, ethnography is both a research approach and a research product. Researchers agree that ethnography does not focus on the culture of a group, but rather on the patterns of a group (Wolcott, 2008), or the beliefs, behaviors, language, and interactions of a group which shares the same culture (Creswell and Poth, 2018). Ethnography is employed when the researcher's goal is to document what actually happens in a natural setting. The data collection typically occurs over a long period of time, and includes a range of data types, with a heavy emphasis on participant observation. Ethnography evolved from the field of anthropology in the early 20th century and its use in education developed in the 1960s and 1970s.

Hammersley (2018) notes over 40 adjectives used to describe various types of ethnographic studies (e.g., collaborative, feminist, insider, longitudinal, rural). However, some of the more commonly encountered types of ethnography in education include autoethnography, critical ethnography, and institutional ethnography. Autoethnography is usually written in first-person and allows the author to examine their personal reflections to illuminate a particular event, culture, or institution. It results in the author's deeper understanding of self (Skott-Myhre et al., 2012). Critical ethnography uncovers the relationships between structures, such as cultural and political institutions and norms, and the agency of individuals and groups (Castagno, 2012). According to Anderson "... the overriding goal of critical ethnography is to free individuals from sources of domination and repression" (1989, p. 249). Institutional ethnography was developed and named by Canadian sociologist Dorothy E. Smith in the 1980s. Institutional ethnographies are created through "the examination of work processes and how they are coordinated, typically through texts and discourses ..." (Devault, 2006, p. 294).

Strengths of ethnography as a research approach include that it can be carried out in an array of settings by an individual researcher, and that it "relies essentially on a human observer to observe humans" (Wolcott, 2008, p. 66). The duration of an ethnographic study is highly variable, ranging from years, sometimes spanning a researcher's entire career, to a much shorter period of a few days to a month, in what Jeffrey and Troman have called a "compressed time mode," which requires the near constant presence of the researcher at the research site (2004, p. 538). A criticism of ethnographies created from shorter time in the field is that they are superficial because the researcher has not had extensive exposure to participants and a fuller range of their behaviors. Access can also be an issue for ethnographic researchers. For researchers in educational settings, the length of time when one can be at the site is controlled by the academic calendar. In other words, there is nothing to observe when school is not in session. Further, research sites which involve the observation of minor children can require negotiation of permissions from multiple sources and levels of administration.

Examples of three types of ethnography commonly encountered in education are given here. In a collaborative autoethnography, [Chang et al. \(2014\)](#) explored how mentoring was experienced and influenced the leadership development of 14 U.S. higher education leaders of color working in faith-based institutions. [Smyth \(2016\)](#) produced a critical ethnography of student disengagement by Australian youth who leave formal education as an act of political resistance. Finally, [Lund \(2012\)](#) created an institutional ethnography of a Finnish university from the standpoint of female academics who are disadvantaged in trying to achieve the “ideal academic” status by publishing in top journals (p. 218). A. Skukauskaitė’s chapter on Ethnography in this volume offers further information pertaining to this method.

Discourse analysis

Discourse analysis, which in its most basic form is the study of language, is derived from the field of linguistics. Writing for the *Linguistic Society of America*, Tannen notes that discourse analysis may be defined as “the analysis of language ‘beyond the sentence’” (n.d., Discourse Analysis section, para. 1). American scholar Zellig Harris is often credited with coining the term *discourse analysis* ([Salkie, 2009](#); [Stanlaw, 2021](#)). He wrote that discourse analysis was valuable in order to study the exemplification of grammar and to focus on how a text sends its messages rather than what the messages within the text may be ([Harris, 1952](#)). Contemporary researchers acknowledge that there are countless variations of definitions for the term discourse analysis, differing in relation to the field of study, specific usage, and scholar’s stances on the method ([Tannen et al., 2015](#)). As a research approach discourse analysis has application across a broad array of fields of study, including communications, anthropology, sociology, and nursing. The 1970s and 1980s saw educators begin to employ discourse analysis in classrooms focusing, for example, on second language learning ([Cohen et al., 1979](#); [Larsen-Freeman, 1980](#); [Lezberg and Hilferty, 1978](#)). Starting in the 1990s, educators used discourse analysis in a critical way to explore the relationship between language and society ([Rogers et al., 2005](#)).

The two primary types of discourse analysis are descriptive and critical. Descriptive discourse analysis seeks to understand how language influences people and situations. Critical discourse analysis seeks to expose through description and interpretation the ways that social inequalities are constructed, maintained, and legitimized ([Mullet, 2018](#)). [Fairclough \(1985\)](#) holds that critical discourse requires an investigation of the ways that verbal interactions are determined by social structures as well as the effects of those verbal interactions on social structures. [Iverson \(2016\)](#) provides a descriptive discourse analysis of sexual assault policies in US higher education using a sample of 22 sexual violence policies from recipients of a 2012 U.S. Department of Justice’s Office of Violence Against Women campus grants. Much of the discourse analysis scholarship in education employs a critical discourse analysis approach. An example of critical discourse analysis can be found in [Thompson’s \(2002\)](#) study conducted with a single music teacher at a government school in Queensland, Australia which “revealed a version of world music based on an ideology of difference” (p. 19). Additionally, [Saarinen’s \(2008\)](#) article on the position of text and discourse analysis in higher education research, which focuses on the construct of quality in higher education policy, may be instructive to researchers seeking further direction on how to use critical discourse analysis. For a more in-depth exploration of discourse analysis, see L. Suciū’s Discourse Analysis chapter in this volume.

Though discourse analysis has become increasingly popular as a qualitative research approach, due in part to its potential for application across a wide array of fields, there are critics of the method. Researchers have voiced concern over its conceptual confusion and frequent conflation of text and discourse ([Schiffrin et al., 2001](#); [Widdowson, 1995](#)). While discourse analysis offers a powerful approach for investigating the use and effects of language, a lack of structure can pose a potential problem for researchers. The creation of new types of discourse (e.g., social media) and technology will no doubt continue to generate an interest from scholars in this “well-established but still burgeoning field” ([Tannen and Hamilton, 2015](#), p. xx) of discourse analysis.

Participatory action research

The term participatory action research (PAR) is considered an umbrella term because it encompasses a range of approaches to participatory action-oriented studies ([Kindon et al., 2007](#)). While participatory action research can involve quantitative data, our focus here is on PAR as a qualitative approach. Deriving from [Lewin’s \(1946\)](#) work on action research, participatory action research combines elements of community-based research, popular education, and action for social change ([Adelman, 1993](#); [Williams and Brydon-Miller, 2004](#)). Brydon-Miller and Maguire state that PAR is “an openly and unapologetically political approach to knowledge creation through and for action” (2009, p. 79). Essentially, PAR is a collaboration between researchers and participants whereby a problem or issue is investigated with the purpose of finding a solution or seeking improved conditions. Key to PAR is its central feature of democratizing research through a partnership between researchers and participants.

The term “participatory research,” the forerunner to PAR, was first used in the early 1970s in Tanzania to describe various community-based approaches to knowledge creation ([Hall, 2005](#)). Since that time PAR has become increasingly popular, particularly within the social sciences. Social activist, author, and educator [Freire \(2005\)](#) whose writings helped form much of PAR’s theoretical framework ([Cahill, 2007](#); [Jacobs, 2016](#)), including “dehumanization; the difference between subjects versus objects in research; co-intentional education, and the ‘banking’ concept of education” was also instrumental in bringing the research approach to educational settings ([Jacobs, 2018](#), p. 45). [Brydon-Miller and Maguire \(2009\)](#) state that PAR works under the concept that ordinary people can learn and transform their own situations and lives via education, action, and research. The authors maintain that

PAR works in education because it “openly challenges existing structures of power and creates opportunities for the development of innovative and effective solutions to the problems facing our schools and communities” (Brydon-Miller and Maguire, 2009, p. 81). PAR is a research strategy which rests on a philosophical foundation of mutual respect and cooperation between the researcher and participants. As such it has been identified as one methodological research approach that is appropriate for historically marginalized or disenfranchised groups such as Aboriginal peoples and communities (Bennett, 2004).

An attractive feature of PAR for researchers, particularly new researchers, is that there are no “hard and fast rules” for how the approach should be implemented, making it easily adaptable to a variety of circumstances and settings (Bennett, 2004, p. 23). When applied in school settings, PAR helps address power imbalances between teachers and students by acknowledging the contributions of students rather than maintaining the traditional view that all knowledge is held by teachers (Brydon-Miller and Macguire, 2009; Jacobs, 2016). Related to this concept of power imbalance is the need for educators and researchers involved in PAR to critically examine their role in the educational process as well as their role in the research study (Brydon-Miller and Macguire, 2009). Failure to thoroughly consider researcher role and positionality can be a potential weakness in the use of PAR. When working in non-school based community settings, researchers must be knowledgeable of the community and sensitive to the agendas of participants. The amount of time that can be required to conduct a PAR study must also be carefully considered and weighed against the realities of the researcher’s responsibilities and time constraints (MacDonald, 2012).

Ditrano and Silverstein (2006) offer an example of PAR in their study involving parents of children with emotional disabilities and a school psychologist in upstate New York. At the outset of the study, the nine parent participants had little understanding of how the school district’s special education system worked and were not connected to support networks. Through meetings over the course of 5 months in which participants got to dialog and think critically about the problems they wanted to address, they moved from passivity to advocacy and action in the school community. Halliday et al. (2019) found that involving students in PAR was promising in helping to understand student well-being. Their research included ten middle-school students, ages 9–11, from a publicly funded Australian school involved in a participatory action research project regarding positive education. Also, Bengele and Schuch (2018) offer insight into conducting dissertations using a PAR approach, including benefits that graduate students might gain from applying the method. E. Stringer’s Action and Community-based Participatory Approaches in Qualitative Research chapter in this volume provides an expanded discussion of PAR.

Conclusion

This chapter was written as an overview or as a starting point to introduce new researchers to seven of the qualitative approaches to research available and applicable to studies in education. Our goal was to synthesize the literature on the five established qualitative approaches of case study, phenomenology, grounded theory, narrative inquiry, and ethnography, as well as two additional qualitative approaches more commonly seen in educational research—discourse analysis and participatory action research—and to present a concise, organized summary of each. With these summaries we hope that the potential for research using one or more of the qualitative approaches begins to take shape in the reader’s imagination. We encourage readers who are inspired by one or more of these approaches and seeking further information to consult the other chapters in this volume, such as M. Hammersley’s The History of Qualitative Research in Education.

Glossary

Qualitative research There is no general agreement about the nature of qualitative research (Silverman, 2021, p. 3). According to the definition which privileges “experience”, qualitative research is concerned with “subjective meaning” as in interpretive research and as opposed to “facts” in quantitative research. In an alternative definition, qualitative research focuses on behavior in naturalistic settings as in ethnomethodology and conversational analysis. In line with this, Silverman argues qualitative research is “theoretically driven, complements quantitative research by [exploring] how social phenomena are constituted in real time, is as much about social practices as about experience, and should be a credible, rigorous enterprise (2021, pp. 4–5). Contrary to this, Denzin and Giardina argue that qualitative inquiry is about changing the world, about advocacy ... that contributes to a public conversation ... a dialogue that puts the very notions of democracy and freedom, citizen and patriot, into play ... the performative and the political intersect on the terrain of a praxis-based ethic” (2012, p. 19). These definitions have important consequences for the practical conduct of qualitative research practice and ethics

Ethics “Ethics” can mean a field of study as well as “the set of ethical principles that should be taken into account when doing social research” (Hammersley and Traianou, 2012, p. 17). “Ethical” can refer to “The realm of considerations relevant to determining what is good or bad, right or wrong ... Here the contrast is with *non-ethical* matters, ...” and “What is good or right, as contrasted with the *unethical*—what is bad or wrong” (Hammersley and Traianou, 2012, p. 17). Ethical concerns in social research commonly refer to certain recognized distinct ethical principles “along with ideas about how these relate to the practice of research” (Hammersley and Traianou, 2012, p. 17). These principles include minimizing harm, respecting participants’ autonomy, and their privacy, offering reciprocity and treating people equitably (Hammersley and Traianou, 2012, points 1–5). The classic informed consent, confidentiality, and anonymity are part of these (Hammersley and Traianou, 2012, chapters 4 and 5)

Paradigms Guba and Lincoln define paradigms as “Basic belief systems based on ontological, epistemological, and methodological assumptions ... The beliefs are basic in the sense that they must be accepted simply on faith ... there is no way to establish their truthfulness” (1996, p. 105). They argue paradigms are not open to proofs in any conventional sense (1996, p. 108), and point to the consequences for practical research, interpretation of findings, policy choices (1996, p. 112) and ethical issues. To illustrate, in positivism ethics is externally audited by codes and committees, in critical theory it is (also) intrinsic by recognizing values and historical situatedness. It is also intrinsic in constructivism by additionally including participant values, but the personal interaction may bring other problems

Worldviews Guba and Lincoln claims that “A paradigm Represents a worldview that defines, for its holder, the nature of the “world”, the individual’s place in it, and the range of possible relationships to that world and its parts ...” (1996, p. 107). As an example, indigenous research illustrates a relationship with the world different from in classic western research, and “deploy interpretive strategies and skills fitted to the needs, language, and traditions of their respective indigenous community ...” (Denzin et al., 2008, p. 11) based on “a commitment to an indigenist outlook” which makes indigenous pedagogies “grounded in an oppositional consciousness” (both 2008, p. 10)

Method talk In the opening of their book, Gubrium and Holstein argue that “the languages of the social sciences shapes how researchers view the world ...” and describe method talk as “the working vocabulary of research procedure” (1997, p. 3). They illustrate by “One familiar idiom directs researchers to a real world of facts and figures. A second urges them to focus on how the real world is conceptualized or formed. Other research vocabularies stake out different empirical terrain. If we accept the tenet that knowledge is humanly produced, it’s not hard to conceive of sites of method talk as knowledge factories—places where the work of knowledge construction takes place. Extending the metaphor, colleges and universities stand out as production sites ...” (1997, p. 3). This illustrates that also paradigms and worldviews shape the way researchers talk about research which make their proponents use alternative vocabularies as in alternative approaches to educational or pedagogic research

According to Gubrium and Holstein’s “idioms of reality”, “It considers the way the language of qualitative method relates to how researchers view and describe social life.” They refer to Geertz’ “The strange idea that reality has an idiom ... leads to an even stranger idea that, if literalism is lost, so is fact” (1997, p. 3). They also refer to Wittgenstein’s “language games” ... in the sense that the manner in which one proceeds to do social research organizes the empirical contours of what is under investigation” (1997, p. 5). Due to the diversity in qualitative research ... each variant is conducted in, a language or idiom of its own. Accordingly, each idiom, presents a distinct reality, virtually constituting its empirical horizons” (1997, p. 5).

Introduction

Research and the research process are shaped struggles over legitimacy and violations. This comes with consequences to research ethics, and with the many positions within qualitative research, as there is no fixed research ethics template (Ryen, 2021). It is by far too complex. Hammersley and Traianou remind us that “there are no single agreed sense given to the term” (2021a, p. 16). Qualitative researchers typically meet up with and work closely with people and write about their lives from settings and contexts that may rhyme, though never fully repeat themselves. This has consequences on how to think about research ethics, particularly when going from theory to the less predictable research practice. When qualitative researchers argue that reality is social, this makes truth a much more complex phenomenon compared to the classic sciences (Denzin and Lincoln, 2005, Guba and Lincoln, 1994 on paradigms, Gubrium and Holstein, 1997 on worldviews and how to talk about qualitative research). This is amplified by the many parallel and conflicting positions in philosophy and the theory of science, which invite alternative positions on issues, such as what research is all about, images of the involved and researchers’ ethical obligations in their relationships with their study participants, including that of writing up their research. This has made the development of qualitative research and formal research ethics far from a linear, unproblematic process within static contexts, but one of critical dialogue and controversies that now range from theoretical concerns to activism and politization, as in class, gender and race studies (Denzin and Gardina, 2009 on qualitative inquiry as hope, Denzin and Gardina, 2012 as advocacy, Haggerty, 2004 on the problems with institutional research ethics government, Smith, 2005 on indigenous research and research ethics, Skeggs, 2010 on feminism and social transformation, Silverman, 2017a,b on research ethics in African contexts). This has made qualitative research a place for reflections on the meeting between ideals and research practice all throughout the research process, as well as social science research permeated by politics at all levels (Christians, 2005 on research and politics, House, 2005 on qualitative evaluation). It has also influenced all research activities, including on how to think about them in ethical research terms, which has made research ethics itself into an arena under constant scrutiny (Fakhry, 1998a on ethics in Islamic philosophy, the many chapters on research ethics issues in Mertens and Ginsberg, 2009). The emergence of new -isms, post-, method talks and pathways in qualitative research raises new takes on old issues by posing new questions to former ways of thinking about research (Carlson et al., 2021, Kuntz and St. Pierre, 2021a,b) and ethics (Tesar, 2021). In a nutshell, this illustrates how ethics is firmly entangled in the wider politics of qualitative research. In the next five sections, this chapter will raise and illustrate such issues, and invite the reader to further reflections relevant to her/his own research.

We begin with providing a brief history of research ethics in the West to help illustrate how the standard code of research ethics came into being and into the social sciences, its justification and the consequences for research. This takes us to the next section on the theory of science and worldviews, in which research itself and ethical ways of thinking are anchored. Research ethics is an exemplary illustration of the impact of politics with the constant friction between institutional requirements and alternative approaches in qualitative research, thus rejecting quick-fix recipes that external committees can follow and tick off, as in much positivist anchored thinking. Then, in the next section, follows two reminders of variations across global regions and disciplines. The third section will in more concrete ways illustrate the implications of philosophy all the way through to research ethics in some paradigms and method talks. This demonstrates in a more systematic way that to think differently about reality comes with alternative ethical research codes anchored in alternative, contrasting worldviews. Denzin and Lincoln (1994, p. 5) reminded us many years ago that the differences we see between them in addressing the same issues return to the politics of research, and to the question of who has the power to claim the right answers to these differences, including ethical research issues. Yet decades later, and as always,

ontologies have taken qualitative research in new directions. We argue that the question of knowledge production makes research ethics a complex and controversial issue. It also means that to learn about research ethics in research practice invites students to become active participants in inquiring into knowledge and knowing, in addition to the impact to their own studies. It also invites the major question: What is research and research ethics all about? In the brief conclusion we reflect on the many turns and world-views in qualitative research. Each new turn brings something new and each new disrupts politics and ethics.

A brief history of research ethics

The last decades came with more external and extensive formalities in research ethics as a response to the abuse and misdemeanors, especially in the name of medical research, though often in collaboration with more powerful co-actors. This provoked reactions that demanded preventive measures with regard to certain questions. This section raises some of these, including: Why all this focus on research ethics? How did it enter the social sciences? Why so much focus on research participants?

From illegitimate medical research to formal research ethics

The introduction of more formal ethical research codes dates to the post-war (WW II) efforts to put an end to illegitimate experiments on human beings in concentration camps during the Nazi regime, under the heading of medical research (Lefor, 2005). This is partially correct, although the roots go further back to when German physicians, who a couple of decades earlier were accused of unethical medical practices in their work with the Nazi ideology of racial hygiene, to keep the Aryan race “pure” through the use of biology (Ruyter, 2003). All criticism of their experiments was ignored. In general, prisoners of war were considered to be an easy target for experiments, but their many experimentation studies also included children, Jews, homosexuals, the disabled, Romani and other ethnic folk groups, etc. The issue of consent was regarded as irrelevant, as prisoners were forced to participate and were often not aware of their participation (such as with the radiation experiments), and with no option to withdraw (Caplan, 1992).

After the war, this led to The Nuremberg Code as part of the court settlement in Nürnberg 1947. The Nuremberg Code or Codex (Nuremberg Code, 1996) consists of 10 rules to prevent such abuses from ever happening again. The first code makes voluntary consent essential, the ninth that the involved should be free to end participation at any time, and the 10th obliging the researcher to end the project in case of harm of any kind to the participant. The focus on protecting participants was a direct response to the historical context, but according to Katz (1996, p. 1662) not strictly confined to this context, as the US judges had more universal relevance in mind.

Despite this, more studies also unintentionally came to put research ethics on the agenda. This included the Manhattan project, which manufactured nuclear weapons. As such, the project was seen as a success, although with devastating effects to Hiroshima and Nagasaki and much more. This makes us ask: When is a research project a success? Does that include how the knowledge is being applied? The above-mentioned project involved researchers, universities, private companies, state leaders, the military, several countries, secrecy and voluntary censorship. This also invites a variety of critical reflections, such as whose past is it (Chakrabarty, 1992), on the rhetoric of historical representation (Rigney, 1990), and most importantly, how does this make us think about research ethics?

Another classic is the “Tuskegee Syphilis Study” 1932–72, with 600 impoverished African American sharecroppers (Reverby, 2009) from Alabama. This was a United States Public Health Service study in collaboration with Tuskegee University. The study was a grave violation of more ethical research issues, and with severe consequences to the involved, their wives and children. This later paved the way for informed consent and US institutional review boards (IRBs) as their ethical research committees. A similar study took place in Guatemala, with several other medical or health research projects taking place across global regions before and after the same war, which involved vulnerable or easy targeted populations, such as prisoners, patients and soldiers. Formal reactions followed.

From medicine to the social sciences

These experiences “paved the way for internal regulations in biomedical research with the Genève Declaration (WMA, 2021a) and the Helsinki Declaration (WMA, 2021b), both passed by the World Medical Association (WMA) in 1947 and 1964, respectively, and both with subsequent versions. Still, further medical misdemeanors followed, which caused the WMA to also recommend formally organized independent ethical research committees (1975) (Ryen, 2011, pp. 417–418). Punch (1994, pp. 88–94) offers a relevant overview over some of the much criticized studies in US’ 1950s–70s social science, including covert research in religious congregations, deception by membership in a sect, a CIA co-funded project where they secretly gave LSD to visitors to a brothel before filming the results by hidden camera, the use of secret microphones to record jury deliberations, Milgram’s classic psychological experiments on authority, in which participants caused “pain” to others (who knew it was fake) in a laboratory setting. Participants were not informed of this. Other countries have their own examples.

The criticism by contemporary researchers also shows that despite international declarations misdemeanors still occurred, that external organizations were also involved, and that studies did cause reactions from both within the research communities and

beyond. There are parallel histories in other countries that paved the way for their own formalized versions of the research ethics regime. Despite common foci, they display variations. There is no overview; therefore, each of us will have to explore the history of our regime. This may better prepare us for potential encounters related to issues of written consent, trust and the assumption of anonymity as the preferred option, and more. Taken together, the above history has nurtured responses (national laws and international conventions), invited research ethics literature (books and special journal issues, separate textbook chapters) and made it mandatory in applications for much research funding. It also has also entered methods courses, insofar as thinking one can strengthen research ethics through education, more awareness, and an improved understanding of such issues. Research ethics is not about laws, although the authority has come to rest with professionalism, and by an externally imposed pressure, until new paradigms in qualitative research emerged that saw ethical care as an internally imposed obligation based on more abstract principles, which commits the morally responsible qualitative researcher. However, there has been an increase in the numbers and issues covered in guidelines, as well as a more intense surveillance. As often described, the net was cast wide, i.e., ethics creep (Haggerty, 2004; Katz, 2007), with new actors entering the stage.

Anchors: from philosophy to paradigms, worldviews, and pathways

All research is anchored in abstract principles that shape how we see the world and explore it; just as qualitative and quantitative research are anchored in different principles, the same goes for the many different approaches within qualitative research. In this section, we will work our way through from the abstract to the concrete and offer a few illustrations to show there is some orderliness in the apparently bewildering chaos in a field where arguments are constantly sharpened, and new directions emerge. The important thing is to understand the longer lines, and to ask questions about our own position and how this informs the politics of qualitative research as we go from philosophy to our own research—research ethics included.

From abstract principles to research practice

These principles or beliefs refer to more abstract ideas about ontology and epistemology, with both informing methodology. Ontology is the philosophical study of the essential nature of reality (Hoffman and Kumar, 2020), or of being (Simons, 2015). This is the most abstract principle and deals with the nature of reality, and belongs to metaphysics, that part of philosophy which examines the fundamental nature of reality. This informs epistemology or the theory of knowledge, which is the philosophical study of the nature, origin and limits of human knowledge (Jupp, 2006), and comes from the Greek terms *epistēmē* (“knowledge”) and *logos* (“reason”) (Stroll and Martinich, 2021), which is concerned with the questions, what is knowledge, how do we acquire knowledge, or how to know the world. In combination, ontology and epistemology constitute the framework for methodology, which is the study of how to do research or the principles that guide our research practices or simply put: How is the researcher going to find out whatever s/he wants to find out, or know? In brief, ontology and epistemology confine the answer to methodology. A belief in a “real” reality demands we leave values behind, as in quantitative research with its various techniques, whereas answers to an ontology that assumes a reality as interactionally accomplished leads to a qualitative methodology with quite different methods. Research methods represent the most concrete level and refer to the specific tools and procedures we use to collect and analyze data. Our position in this wider landscape informs the research principles and procedures we use in practice just as in feminist research on women’s experiences which politicized research. This calls us to reflect on the question: What is my position in this landscape?

Firstly, taken together, the answers to the researcher’s ontological, epistemological and methodological basis make up nets described as paradigms or interpretive frameworks that guide research (Denzin and Lincoln, 1994, p. 13) or worldviews, which specify their own directions or positions in qualitative research that guide research practice. Others refer to method talks (Gubrium and Holstein, 1997, p. 100). They all bring their own language and concepts, which work as rather distinct approaches to inquire into social phenomena and make them recognizable to us as realities of some kind out there.

This is the topic of the next section. Importantly, these nets or various positions also inform us as how to think about research ethics and teach us how to be morally committed researchers. As we shall see, this makes research ethics varied, complex and intricate, a point often ignored in institutional ethical research arrangements.

Globalization made the world smaller, but also more diverse.

Philosophical wealth: ontologies and epistemologies from across the world

All societies come with a variety in formalized philosophical traditions and systematic thinking, whether referred to as “philosophy” or not (Ames, 1998). Global regions show long oral and written traditions, which in their own ways inform the politics of qualitative research, and how to work ethically in their impact fields. Philosophy has been sorted by its position in historical time as in Ancient- and Modern philosophy, but there has also been a tendency to appeal to regional categories such as Western, non-Western, Eastern or Oriental philosophy, or even the more specific Greek, Chinese and other philosophies. Such categorization may serve its functions, yet also comes with a tilt toward undue simplification. History shows that regimes, philosophers, and ideas have traveled along with the history of conquests and traveling routes, where philosophies were inspired by theories from across regions. Philosophical works were also translated, such as Aristotle’s works into Arabic, which caused Greek philosophy to have an impact on Islamic philosophy (Fakhry, 1998a,b). Further, Copernicus traveled to Italy and encountered Islamic science before

he developed his revolutionary idea of no longer seeing the Earth, but rather the Sun as the center of the cosmos. Moreover, the Prague astronomical clock, or the Prague Orloj, was inspired by Islamic science. In social science the history is more complex, and as always also due to internal controversies also outside European philosophy (as reflected in [Sardar, 2006](#)).

Despite this richness, and despite the many diasporas, courses and studies in Western higher education have been criticized for a tendency to focus on philosophers from their own region without being explicit as in the difference between “Philosophy” and “European Philosophy”, until philosophies from outside Europe eventually entered Western universities ([Van Norden, 2017](#); [Kim, 2013](#)) and inspired dialogues across regions ([Angle and Slote, 2013](#); [Taebnia, 2021](#)). This reminds us of the very long history of science and of philosophy beyond Europe ([Park, 2013](#)), as in the case of prominent Arab historian Ibn Khaldun (1332–1406) and his work on the philosophy of history ([Khaldun, 2012](#)), described as a landmark of social thought ([Issawi and Leaman, 1998](#)).

Even though this chapter draws on Western thinking, the essential message is that research ethics is philosophically rooted, that the multitude of theories reflect alternative and conflicting positions with their own assumptions pertaining to ethical research issues in qualitative research. The risk is the further universalization of research ethics, one of the classic objections to how it has institutionally been managed regardless of research participants, contextual matters and translational issues ([Wodak, 2011](#)). This includes the criticism of hierarchies and hegemonic knowledge, in this case with committees over qualitative researchers ([Hammersley, 2009](#)).

This reminds us that philosophical and cultural roots also inform our study participants in everyday matters, such as relations with strangers, respect and communication, as it plays in social meetings between participants. If unfamiliar, we as researchers need more time and experience to learn doing being moral inquirers ([Ryen, 2001](#) and [2007](#)). If politeness to guests overrides straightforward speaking, then answers to our simple questions will need interpretation to achieve a mutual understanding. It may be helpful to read about other researchers’ experiences in the relevant culture in order to help prepare us prior to going into the field, such as the many chapters in [Barnard and Wang \(2020\)](#), the citations from others’ studies (as in [Silverman, 2013](#) or [Johnson, 2020](#)), and when writing up your document ([Baker et al., 2016](#) in nursing).

Brief reminders on traditions and practices

Qualitative research means different things to different people, and [Denzin and Lincoln \(2005, p. xv\)](#) remind us that the discourse in qualitative interpretive research moves in different directions at the same time, which creates “new spaces, new possibilities, and new formations for qualitative research methods while closing down others”. This tells us that the social in social science makes it incongruent with dominant principles in classic science, and that the internal diversification within qualitative research is a continuous process. Worldviews address the world and the same issues in it, but in systematically diverse ways, always returning to the politics of research which accordingly frame research ethics.

As part of this, globalization has reminded us of the universal/local disputes, and that qualitative research is always situated. It takes place with people, somewhere and within certain contexts. This calls us to be aware of what these are, as well as the implications to our own studies.

First reminder: histories and traditions in qualitative research

In qualitative research, conflicts between distinct parties with incompatible arguments are the norm and not the exception, as we saw with regional, national and disciplinary traditions and dividers. New thinking occurs at the turning point between theories, not in the comfort zone. What feminism saw as constraints in positivism defined the fields and took them in different directions and still does. This is how the basic metaphysic belief systems lead to paradigms or worldviews ([Denzin and Lincoln, 1994, p. 107](#), [Guba and Lincoln, 1994, p. 107](#)). People within each talk about the world and about research in their own ways which has caused [Gubrium and Holstein \(1997\)](#) describe these as “method talks”. Each brings its own rhetoric particularities and idioms that reflect its philosophical position and constitutes social reality its own way.

The history of qualitative research has been categorized into successive phases, although authors tend to talk from their own site location as if these phases and time of origin are universal (as in [Denzin and Lincoln’s “moments” in 1994, pp. 7–11](#), and in [Vidich and Lyman’s “Qualitative Methods: Their History in Sociology and Anthropology” 1994, pp. 23–59](#)). Both offer great insight, but into aspects of the American history of qualitative research. This is not about persons, but instead what [Atkinson et al. \(2011, p. 467\)](#) refer to as “a pervasive problem in the international circuits of awareness” in their article on European traditions in biographical research. They point to the problem that researchers tend to only know their own national context. [Atkinson](#) previously ([2005, p. 2](#)) reminded us that:

While the global character of academic publishing has meant that English-language research communities have dominated much of the discourse, and American work has been especially prominent, in fact there are strong and distinctive national as well as disciplinary traditions.

Due to a lack of more publications, the implication of these traditions to research ethics is not yet clear, so therefore it is all the more important that we investigate into and reflect on the relevance to our own research. Textbooks may easily make us assume they are universally applicable as they are.

Second reminder: what to do and what you do

Official ethical research guidelines are general in nature, and for practical reasons. However, encounters are emergent and cannot be foreseen differently from what ethical research forms make us assume. This is about principles and practices. How we see the world, how we respond and how we represent it is also informed by cultural and other scripts. This also applies to research ethics, though it is often ignored in contemporary ethical research regimes.

A philosophy that differentiates between descriptive and normative ethics is most relevant here. The concepts are telling. [Kitchener and Kitchener \(2009, p. 5\)](#) put it simply:

Descriptive ethics studies how people actually behave and what ethical values they actually hold. This area belongs to empirical social science. Normative ethics is concerned with the questions: How should an individual behave; what properties are valuable and good? In short, whereas descriptive ethics studies the “is” side of the is-ought distinction, normative ethics studies the “ought” side.

This makes applied ethics deal with “principles ... from normative ethics to resolve specific moral issues in concrete and particular settings” and “social science research ethics an example of applied ethics” (2009, pp. 5–6). Applied ethics sorts itself under normative ethics because it deals with practical questions or principles used to solve concrete ethical issues ([Blackburn, 2016](#); [Crisp, 2011](#)). Worldviews and cultures diverge in what we see, and how we see it. What some see as good and acceptable, others may find immoral. It follows from this that we also diverge in how to resolve specific moral issues in concrete and particular settings. This is reflected in the contrasts between the paradigms and worldviews. This causes ethics and politics in qualitative research to become entangled, which accounts for the variation in what appears as ethical issues or not, and morally acceptable responses or not. [Elizabeth Murphy and Robert Dingwall \(2010, p. 339\)](#) remind us:

The ethics and the politics of ethnography are not clearly separable. Questions about the right way to treat each other as human beings, within a research relationship, are not wholly distinct from questions about the values which should prevail in a society, and the responsibility of the social scientist to make, or refrain, judgements about these ... Our assumptions about the nature of reality, the possible knowledge of that reality, the truth claims and so on, all have significant implications for our judgements about the ethnographer’s responsibilities The lack of consensus about methodology in and about ethnography, is reflected in discussions about its ethics.

This is not confined to ethnography, but ethnography appears as more complex compared to other methods, due to the character of it and the many questions that follow. It also illustrates the division between positivism and the many constructivist approaches. Positivist principles constitute what qualitative researchers initially reacted against, and nurtured alternatives. We will now illustrate the implications.

Politics and ethics entangled

Let us briefly recall the major idea in- and concepts associated with positivism, which has gained renewed relevance albeit now as politicians’ favorite. The reactions to the implications of positivist philosophical anchors, and the associated politics of research, initiated the responses and alternatives in constructivist research. It is this that makes “qualitative research mean[s] different things to different people,” which we will now illustrate.

Positivism: external reality and pre-packed ethical issues

Classic positivist ontology is inspired by the philosopher René Descartes on reason that developed the natural sciences. This rationality comes with an ontology that reality is “real,” externally out there. Epistemologically, this implies a dual thinking with methodological approaches that look for truth/not truth, or for the ways things are (and not). This is the background to the scientific revolution that followed, in which William [Bristow \(2017\)](#) reminds us that to Descartes, “all knowledge, in a relatively simple and elegant rationalist metaphysics provides a model of a rigorous and complete secular system of knowledge,” which led to “The Age of Reason” or the idea of Enlightenment in the 18th century. Reason came with attacks on dogmas in science, metaphysics and religion, and with a strong belief in the intellect to acquire a systematic knowledge of nature. Empiricism is another keyword for that era, along with a strong optimism. This simply means that natural science slowly departed from metaphysics and became the dominant worldview in all research. Even so, there was also a widespread skepticism within philosophy, which makes these “new” ideas by far more complex than what is often presented in the social sciences. The essence is that it marks a profound change in thinking about nature, and in how to obtain knowledge about the world. This is a simple description of positivist quantitative research (see [Christians, 2005](#), pp. 139–144 on the Enlightenment, autonomy, Rousseau and Mill), but it captures the key elements in our context.

In quantitative research, this has been translated into guidelines to help provide analytic results we can generalize beyond the sample in search of true, lasting knowledge. This is based on the assumptions that there is a stable and external reality. This ontology

demands control of all matters that may cause bias and skewed results, or in other ways interfere with research as neutral and objective. The stimuli-response model demands all respondents to be exposed to the same question. This explains the weight given to find the correct question formulation in survey research. It also explains the weight on instructions and training in correct interview behavior to maintain a distance to the respondent to avoid influence. Some textbooks are even more specific through instructions on a dress code to appear as neutral and minimizing outside informal talk beyond the interview questions, and to control your emotions. All of this is considered as a possible source of contaminating data. Such instructions reflect a particular image of the world, of the participant and of normative principles of our relationship with those involved in our studies. To assume that knowledge is objective makes the researcher into the authoritative knower also when writing up research. In this paradigm, the importance with participants is to gain access to the relevant data they already carry with them, hence data “collection.” Our interest is with them as containers or “vessels of answers” (Gubrium and Holstein, 1997, p. 65), and it follows from the according epistemology to keep a distance, to not get involved, to control one’s feelings and to never become emotionally involved. This makes research ethics external and more straightforward as in much contemporary formal research ethics. However, in contrast to historical violations, participants are now entitled to become informed about the study and to be asked for their consent to participate, trusting that the researchers will treat the data as agreed upon and otherwise respect them. They are also free to drop out whenever they desire. In this worldview, ethical research protocols share principles based on the same ontological anchor as in biomedicine, with laboratory studies with individual participants in a rather manageable process. To illustrate, the US history of evaluation has been quantitatively dominated with a view on science and morality as separate and on evaluation as apolitical. This caused House (2005) to argue that social justice concerns have been “routinely omitted from evaluation discussions” (p. 1074) due to the evaluators’ unfamiliarity with philosophy and the affiliations with “politics” (p. 1075). And, by his “interest in the normative political characteristics of ethics in evaluation” (p. 307), Schwandt (2018) challenges this apolitical character of professional ethics in traditional evaluation. Another classic, the PISA (Program for International Student Assessment), is “the largest international study of education, examining the reading, mathematics and science achievements of students as they approach the end of compulsory schooling” (<https://www.erc.ie/studies/pisa/>). Here, Sjöberg and Jenkins (2022) point to the political character by the impacts on national curriculum policies, through politicians’ suggestions to modify school curricula to maximize PISA performance (p. 10).

Qualitative researchers see positivism differently. Post-positivist, constructivist researchers argue that it is reductionist, deterministic and simply naïve.

Ethnomethodology: doing being ethical as collaborative accomplishment

Professions such as nursing and social work tend to refer to phenomenology that draws on Husserl and Heidegger. They also refer to Alfred Schütz on interpretation when they interview about meaning to understand experience—a commonsense notion, but David Silverman argues they have misunderstood Schütz who would study commonsense reasoning as a topic “rather than to rely on it as a tacit resource” (D. Silverman, 2017, p. 148) so crucial to Harvey Sacks who developed ethnomethodology further. This reminds us of the complexity of philosophical theories. Sacks (Silverman, 1998) in his critical dialogue with Schütz’s theory, moved away from phenomenology and developed ethnomethodology where researchers analyze taped talk without meeting their study participants. The interest is with ordering or the practices through which lived order is organized (hence the “doing being”), according to Pollner and Emerson, “a measure of analytic distance” (2010, p. 124). This makes certain ethical strengths often pass without seeing.

Firstly, the distance to the members involved makes the classic ethnomethodologist stay indifferent to whatever participants say, but also become worried about getting involved with members’ concerns. This is easier when analyzing taped talk compared to when working ethnographically. Secondly, in ethno-related research on taped data there is much member interaction, but no researcher-participant interaction because they simply do not meet. This reduces ethical risks. On the other hand, critics would argue that they do meet, but their relationship is a textual one. They would also argue this still leaves the researcher in control of analysis and the final text. The researcher also negotiates access to the organization and gatekeepers, who then negotiate with potential participants. This causes ethnomethodology’s indifference to be conditional, as they do not escape research ethics issues.

Still, this approach brings an ethical research strength that often passes unnoticed. We may draw on Paul Atkinson and David Silverman (1997), who point to the prevalent failure not to recognize the “work” participants do in most interview studies. To help illustrate this, patients in the emergency room often have several problems, while the doctors’ “What can I help you with?” usually diverts only one of the patient’s problems. In John Heritage’s sequential analysis of talk in the emergency room (in Silverman, 2007, p. 116), he finds that doctors tend to ask patients one of two questions:

Do you have any other medical problems?

Do you have some other medical problems?

The analysis shows that “any questions” tend to elicit much fewer questions compared to “some questions” (not shown here). Such details only available and noticeable on tape tell us that patients tend to hear “any” and “some” in quite different ways. “Any” is heard as if the doctor expects no further questions, as opposed to “some.” This makes “some questions” more patient-friendly. The

interaction is shared with the reader, as the patient's talk is just as important as the doctor's talk, and their joint *in situ* data (usually not shown in other method talks) make the analyst avoid jumping to conclusions based on interpretations of patients' stories about their experiences. All talk is available to the reader and the analytic strategy does not interpret talk, but rather members' methods in creating social order. Extracts of sequential talk also make it easy for doctors to recognize themselves in such natural contexts (though the simple example above illustrates our point) (see Silverman, 2007, p. 116). For more illustrations, see Drew and Heritage, 1992, Ryen, 2009 for Sacks' MCD analysis, Heritage, 2018, Drew, 2018. This shows that data on "knowledge-in-action" also makes it easier to invite the professionals to discuss how to improve their own practice to the benefit of the patients.

Thirdly, this illustrates the entanglement of epistemology, analytic strategy, and research ethics, which invites the question: Can an analytic strategy itself be unethical? (And, what about positivism?). In this view, much feminist research concerned with voices is regarded as analytically inadequate due to treating these as unmediated descriptions used as a resource for the researcher. When ethnomethodologists argue this as being naïve, it reflects an epistemological disagreement. When feminist research assumes a special ability in "unmasking delusions" as Silverman describes it (1993, p. 179), their failure, he continues (1993, p. 181) is "too often ignoring what people actually are saying and doing." He reminds us (1993, p. 181) "not to confuse actor's accounts with sociological [or other disciplines'] analysis" (for further discussions of interpretivist, constructivist thinking and philosophical roots, see Schwandt, 1994, pp. 118–137). They would argue that all qualitative research that assumes responses to be authentic and simple truth claims fails. A major argument is that data must be analyzed, and not simply reported. We will later see that critical feminism counters such accusations. Fourthly, through the apparent micro-orientation of this philosophical position, it offers us the ability to analyze how the wider contexts, such as school policies, advise dealing with Covid-19, or that everyday circulating images and concepts enter ordinary talk by studying how social reality gets accomplished. This makes the argument that it ignores power irrelevant, just as we saw above in the example on making the hidden in doctor-patient talk visible.

As referred to, such detailed interactional data are frequently used for educational purposes with professionals and others. Conversational analyses (CA) of access to public services in emergency service calls in general (Svennevig, 2012) or calls with native—and non-native speakers in which language differences may complicate the interaction between call takers and callers (Garcia, 2021), illustrate this well. To learn how to improve such interactions will better prepare call takers to avoid occurring challenges in such calls. Others have investigated how couples manage conflicting knowledge claims when one of the persons has dementia (PWD) (Landmark, 2021). Such analyses will help educate carers and family members in how to deal with such issues and still treat PWDs as competent conversational participants (p. 208).

When researchers within this method talk work ethnographically, they will face much the same ethical challenges that others do (for references see Pollner and Emerson, 2010, for analyzing mobile talk see Ryen, 2008, research ethics in ethnography work 2012, and see Roulston, 2018 on her students' experiences in online coursework). This opens to more nuanced analyses of power plays, and how hierarchical thinking plays out in practice (Ryen, 2019a). This framework is also employed in feminist research on focus groups (Wilkinson, 2021) and as we saw in Conversational Analysis (Kitzinger, 2000 and 2007).

Constructivism: rejecting old scripts

Reality as interactional products makes ethical issues emergent and most evident in ethnographic work. This makes qualitative research a most heterogeneous category. Both ethnomethodology and the social construction of reality are seen as disciplinary extensions beyond the social phenomenology of Alfred Schütz and developed further by Thomas Luckman and Peter Berger as a study of things as they appear through the acting subject's perspective. This rejects the positivist claim of objectivity and makes knowledge a human construct. We recognize this in philosophy of science by Thomas Kuhn on changes in paradigms, in Wittgenstein on language games, and in Joe L. Kincheloe's influential critical constructivist epistemology in education (Kincheloe and McLaren, 2005, pp. 303–342). It also implies a criticism of standardized ethical guidelines as universal and with standardized solutions readily available to external persons. Rather, as interactional outcomes, ethical issues are emergent throughout the whole research process. This calls for self-reflectivity both within and across cultural contexts and calls for reflection on issues like (Ryen, 2019a, p. 192): "Who am I to others? What am I a part of? Do I want that?", and Fazal Rizvi who claims that "Knowledge claims are, if you like, preceded by questions" (2009, p. 112) such as "who is this 'our' that is being talked about?" and "does it include me?"—and if it doesn't then, "how is language being used to marginalized people?" (2009, p. 109). Ethnographers argue their research ethical strength is with bringing in contextual knowledge which may uncover issues like hidden power. This also deals with protecting participants from harm and their concern with participant rights. However, the individual—collective of rights reflects a historic moment in the Western society with autonomy and self-determination, and reminds us of the local contextual of contemporary codes and regulations. To illustrate, by ignoring ethnographers' sensitivities to methods specific issues, they may rather increase the risk of harm.

The historical background to formal research ethics paved the way for a focus on the classic concerns with codes and consent, confidentiality, and trust (Faden and Beauchamp, 1986). Ethnographic work has showed these as much more complex than assumed (Stake and Jegatheesan, 2008; Ryen, 2021) captured in Guillemin and Gillam's (2004, Baker et al., 2016) "ethically important moments" (p. 262) in "ethics in practice" (p. 264, Renold et al. 2008) different from committee talk. Consent presupposes knowledge about what it means to participate, what it is that you consent to, that you can evaluate benefits and risks, understand what it implies to consent when reusing archived material if relevant, and the symbol of signing a document. If local procedures allocate actual consent with a gate keeper the potential participant finds it hard to oppose, things get complex. We simply get entangled in local authority—and loyalty webs despite participant consent as captured in Sabari and Ben-Yehoshua's title

(2017) "I'll sue you if you publish my wife's interview" on life story research in Israel. The emergent of ethnographic encounters have made ethnographers rather prefer a process consent procedure over an initial consent form at the start. Other issues such as data ownership and control over analysis and interpretation linger on (Ryen, 2021, p. 37). Further, not all regimes demand written consent, and historic memories of betrayal and "signing away" may invoke distrust with signatures. This reminds us that research ethics with confidentiality/anonymity and trust are more complex than assumed in formal codes based on a quite different ontology (Ryen, 2021, pp. 39–41, see Olesen 2005, pp. 235–278 for challenges in feminist research, and Lincoln, 2009, pp. 150–169 on the many shifts in ethical frameworks in qualitative research, Mertens and Ginsberg, 2009). Codes assume that participants want their participation to remain confidential, but some 'do want their names in the report in accordance with regional traditions, to prohibit their stories from being taken away from them or for assuming being published may open opportunities. To ignore such requests may appear as patriarchal and disregard of local preferences, or the researcher may wrongly assume lack of awareness of potential consequences of disclosure, or of other risks. Despite consent, confidentiality may be tricky in small places and participants easily detected by journalists, or people may react to the report for other reasons (Ellis, 1995). Murphy and Dingwall (2010, p. 340) also remind us to be cautious of any cathartic effects of research interaction often claimed by feminists. And, if ethnographers document how participants adapt to structural and institutional pressures, people with power may use the report "to control and manipulate those without" (2010, p. 341). This shows that ethnographers have discussed interpretive and representational authority even prior to the postmodernist turn. This reminds us of the regional of Western philosophical anchors and ethical regulations (see Liamputtong, 2012, Nortjé et al. 2019; Trimble and Fisher 2006; H. Silverman, 2017). Such experiences and arguments reflect the close and complex relationship between philosophical anchors, politics, and ethics in qualitative research (Bauman, 2005, pp. 1083–1098, Christians, 2005, pp. 139–164). The politics of constructivist ethnographic research make visible the intricate of field relations and the subtleties and messiness of fieldwork (Delamont, 2007, pp. 2–4).

Stanton Wortham and Kara Jackson remind us that there is a vast variety in the certainties that constructionists presuppose, including in educational constructionism (2008). They remind us that, "Various objects are constructed in educational processes, such as the identities of teachers and learners, the subject matter learned, and the social structures produced and reproduced"; this takes place through mechanisms at different organizational levels and include "psychological, interactional, cultural, and social elements" (p. 107), and that such studies may contribute to transform education (p. 107). Gomez (2016) on working with the Roma Community, and Hurd (2019) on mixed identity illustrate Wortham and Jackson's points above well.

The politics and ethics of much interpretive research overlaps much with that of more action-oriented approaches who more explicitly flag their transformative aim. However, as to the very pursuit of research, they follow separate pathways. This calls for a sub-section of their own.

Feminist and indigenous research: community grounded research ethics

Joe L. Kincheloe's argued his critical constructivist epistemology is important to becoming an educated person and to social change and—justice. These political and pedagogical arguments became crucial for the movement of critical constructivism in the 1990s onwards concerned with political struggles and power in knowledge construction, and the perspectives of oppressed peoples. It makes emancipation or transformation the very task of research as in feminist and indigenous research based on his critical ontology which brings a new constellation of politics and research ethics with research endowed with a moral obligation toward social justice based on their own worldview free from the burden of classic academic scripts (Hesse-Biber and Nagy, 2011; Hall, 2021; Kegel, 2011; Loomba and Lukose, 2012). With the researcher as bricoleur (Kincheloe and McLaren, 2005, pp. 316–317) s/he will use all tools available to unpack the relationship between his/her way of seeing and the social location of his/her personal history. This makes the relationship between individuals and their contexts crucial to uncover the invisible inherit in power and culture (2005, p. 317). This includes to become aware of epistemological presuppositions that inform both our research and our own thinking (2005, p. 305) as with the authoritative research ethics codes and calls for Freire's pedagogy of the oppressed to eradicate perpetuating oppression. It argues truth as discursively situated and implicated in power relations (2005, p. 327, Jakobson, 2016). This applies to both feminist and indigenous research as reflected in their ethics of care.

Feminist prescriptive ethics implies to treat participants with respect in all phases of the research process and includes reciprocity, honesty, accountability, responsibility, equality etc. (Skeggs, 2010, p. 433). The American grown ethics of care is a feminist relational philosophical perspective and a distinct normative moral theory based on the experience of care and care work adopted by many American feminist and other "post-" researchers. It has faced much criticism by feminists and others and seen as regional by reflecting a particular culture that appeals more to Americans than to Europeans as in Hammersley and Traianou's criticism (Hammersley and Traianou, 2012). Feminist research, always concerned with power—how it works and how to challenge it (Skeggs, 2010, p. 426, Atanga, 2013), defends values of reciprocity, equalizing power control, and conscientization (see Skeggs, 2010, p. 435 for criticism). These values also inspired indigenous research though feminist research has pinpointed some more problematic links between politics and ethics related to the need to translate women's voices from talk to text. This refers to the issue of texts as representations of true experiences and relates to the meeting between epistemological-analytical and activism. In practice, some handled this by looking at discourses and ways women represented their stories, others kept them "raw" due to their political potentials. These debates later initiated new experimental representational practices including poetry, theater, assemblages etc. which enlarged the cleft between other epistemologies and feminist activism, but also inspired indigenous researchers to reject old epistemological constraints based on the much-criticized Enlightenment period (Israel, 2010). Feminist and indigenous researchers both use past experiences in their fight for a different future. They draw on their own history and

experiences from which new, different ethical principles grew in respect of feminist and indigenous research as a counterhegemonic activity for social justice. The latter speaks from within an interpretive community based on its own historical research traditions and claims a need not only to resist, but also for reordering and redefining themselves as “we” see “ourselves”, not as another “other” (see Ryen, 2019b). Indigenous scholars and activists including Linda Tuhiwai Smith (2005/2012), Bishop (2008), Kovach (2009), Marie Battiste (as in Battiste and Henderson, 2000, Denzin et al., 2008 Part IV Power, Truth, Ethics, and Social Justice pp. 439–458) insist on indigenous peoples’ control over their knowledge and heritage based on guidelines developed by their tribal communities and indigenous worldviews. Denzin and Giardina (2012, p. 20) concerned with pedagogics refer to a praxis-based ethics, an ethics that resists oppression and which enacts a hope of possibility “grounded in performative practices that embody love, hope, care, and compassion”. This demands that indigenous people—not only individuals—shall be informed that research is being carried out on, among and with them, researchers will need training in relevant research protocols, and it is required that the community shall benefit from research. Despite internal variations, indigenous researchers have for political reasons decided to speak with one voice just as in early feminism. It is no longer about interpretations, but about change (Denzin and Gardina, 2009, p. 13). This turn, as with all battles, undermines internal relations more beneficial to some than to others, and this social justice refers to protecting the many over the few. So far, researchers and participants will have to comply with that.

Storytelling has been important in both feminist and indigenous research. To help illustrate, in her article, “de-colonizing practices: Negotiating narratives from racialized and gendered experiences of education”, Phoenix (2009) refers to postcolonial feminist work when she draws on Caribbean serial migrants’ narrative accounts to “examines how (post)colonial legacies intersect with racialization and gender in experiences of education to produce subjectification as racialized and gendered subjects” (p. 102). Also, indigenous research draws on storywork as in Pedri-Spade’s (2016) performance ethnography, where Anishinabe participants share stories, sing and drum. This is part of a critical pedagogy with an emancipatory potential, in which both analytic quality and research ethics rest with indigenous ways of knowing and doing.

Conclusions

We are once more reminded of Murphy and Dingwall on “The ethics and the politics of ethnography are not clearly separable ...”. Changes in images of the participant, of research relations and of the purpose of research, make research ethics more complex and the dominant guidelines less adequate. In “Proclaiming the New” (Kuntz and St. Pierre, 2021b in their 2021a) Marek Tesar in his « -Philosophy as a Method» (2021) argues that “the core of philosophy as a method is the ethical relationship with a thought” (p. 545). He urges the reader to work with original texts. He turns and returns to Decartes, Dewey, Freire, Deleuze and many more, and by “What is Philosophy?” (p. 252) he emphasizes the question mark and asks: “After the linguistic turn, the cultural turn, the historical turn, the post-structural turn, and the post-human turn, where do we turn?” (p. 252). The question mark is important because these turns is what drives qualitative research. Each turn destabilizes politics and ethics and brings something new.

Glossary

Counter Storytelling A narrative approach to qualitative research that draws on Critical Race Theory to unmask racialized experiences and reconstructs narratives from the views of the oppressed to arrive at a more complete understanding of oppression and social change

Critical Ethnography A qualitative research tradition with roots in the 1930s community sociologists and in the 1960s action anthropologists that contribute to critiques of racial and class inequalities with research narratives of oppressed communities that were more asset-based rather than deficit oriented

Critical pedagogy A teaching approach that brings together critical theory and educational practice in order to help students question and challenge dominant beliefs and practices for higher social, critical consciousness

Critical theory A processes of critique of knowledge and power aimed to transform practices in society. Critical theory is not a research method, but has lead philosophers and qualitative researchers around the globe to challenge oppression, question neutrality, and engage in collective social action toward justice.

Dialectic Initially conceptualized as a Socratic technique of employing discussion, reasoning, and, therefore, dialog to expose false beliefs, Hegel applied the dialectic to mean a critical investigation of the process of change resulting in the theoretical application of such a process to the social sciences. Domination—The exercise of ruling power with supremacy or preeminence over another

Duoethnography A qualitative ethnographic approach that engages researchers in a dialog with each other and educational texts or artifacts that examines power, privilege and improving conditions of teaching and learning

Exploitation The act of making use of another in an unfair or mean manner for one’s own advantage. Inquiry—A systematic investigation and examination of facts or principles

Participatory Action Research An approach to qualitative research that involves researchers and community or school stakeholders collaboratively questioning and acting on structural issues of power and the inequitable distribution of social and material resources through solidarity work

Praxis A union of action and reflection and of theory and practice; critical praxis in education refers to a threefold process of self-reflection, reflective action, and collective reflective action for social change

Introduction

Critical theory in qualitative research in education

Critical theory, involves critique of knowledge and power aimed to transform practices in society. It has a long history of informing and shaping diverse qualitative research practices. Critical theory itself is not a research method, but a way to think about, know, and relate to the world with an eye toward inequitable social relations (Kinchloe and McLaren, 2011). Such a theoretical lens—both for educational researchers and otherwise—has proven valuable in: (1) exploring power relations that lead to unjust distribution of social and material resources by institutions, groups, and individuals based on economic, racial, and gender hierarchies (among others); (2) challenging qualitative researchers to question more positivist approaches that can inaccurately assume scientific neutrality among objective observers by engaging researchers in more reflexive research practices that question the biases from which they view the world; and (3) situating collective social action that challenges oppression. Through using critical theory, qualitative researchers can push educational reform for the better of all humanity.

Critical theory: an overview

Although it is difficult to point to one, universally accepted critical theory that all critical philosophers have embraced, critical theory has its roots in both the legacy of Western theoretical traditions including the Frankfurt School, and has been enriched and extended by philosophers in global contexts through growing schools of thought and processes of critique. Globally, critical theories share epistemic and ontological orientations toward transformative knowledge and practices.

As a philosophy within the social sciences, critical theory often refers to the prolific work of several generations of German thinkers belonging to Western European and Marxist traditions, many of whom are members of the Frankfurt School. Philosophers of the Frankfurt School moved away from traditional theory by seeking to reconstruct the meaning of human emancipation radically through what Max Horkheimer has described as “liberat[ing] human beings from the circumstances that enslave them” (Horkheimer, 1972: 244). Critical theory is liberating through the processes of historicizing, critiquing, and exposing the relationships of domination and subordination and the contradictions of human experiences. Such critique focuses on deconstructing how knowledge is produced, whose knowledge is valued, and how control of such knowledge equates to power in society. This critique prevents people from becoming slaves to the ideas and activities that societal institutions push upon them. Because of this search for a theory that—through critique of social constructs—could articulate freedom for all, while arguing against the suppression of human consciousness, multiple and diverse critical theories have developed since the birth of the Frankfurt School, including (but not limited to): critical race theory, critical pedagogy, critical literacy, critical feminist theory, etc. (see the section titled **Global critical philosophies**).

Viewed as a process of critique or method, we may also define critical theory as a type of self-conscious means of addressing the need for dialog and a dialectic approach around transformative, emancipatory practice. Such a process of critique pushes theorists to question continuously how they look at—and depict—the world compared to how the world actually exists, and, as a result, challenges theorists to question the very theories they form through such a process. According to critical theory, when a philosophy fails to question wider society and problematize oppression, it has become an ideology in need of critique. The Frankfurt School valued the use of such inquiry or critique as a tool for praxis—therefore, interrogating and engaging the relationship between theory and society.

A brief history of critical theory and the Frankfurt School

The best way to understand critical theory is to first locate it within Western philosophy’s historical trajectory. In doing so, one finds that we can trace critical explorations of knowledge production that form the framework of critical theory today back as far as 2500 years before the first critical scholars.

European classical philosophers

We can find a critical approach to understanding the relationship between knowledge and power in society in the work of the Greek philosophers Socrates (469–399 BC), Plato (428/427–348/347 BC), and Aristotle (384–322 BC). Through Plato’s dialogues—most notably *Gorgias* and *The Apology*—one can see how Socrates (Plato’s mentor) questioned the way the Sophists (classical Greek philosophers who exercised great power in Athens) used rhetoric to persuade people to manufacture and believe in false truths, rather than use rhetoric to search for ultimate truth for the better of humankind. Similarly, Plato’s determination to record Socrates’ stories through the written word—despite Socrates’ skepticism about the technology of writing—reflects how Plato recognized the importance of language as a meaning-making tool for the development of critical thought. Following Plato, Aristotle theorized and deconstructed the power of knowledge creation in language manipulation through *The Art of Rhetoric* and *Poetics*. Aristotle outlines the process of writing persuasive speeches that appeal to *logos* (reason), *pathos* (emotion), and *ethos* (confidence in the orator’s personal character). Although thousands of years would pass between the lives of these Greek philosophers and the foundations of critical theory which grew out of the Enlightenment, the examination of linguistic tools in knowledge production that were explored in Socrates, Plato, and Aristotle’s work proved invaluable to Western philosophy traditions.

Kant, Hegel, Marx, and modern foundations of critical philosophy

Following the Middle Ages in Europe—that marked the hegemony of the Catholic Church—and the European Renaissance, that marked the break from this Church’s control, came the birth of the Enlightenment in Europe and America. During this era, Immanuel Kant (1721–1804) highlighted the value of critique as the only way to find true knowledge and combat illusory ideologies by separating the self from the dogmas surrounding us and by questioning those concepts that are presented to us as facts. Georg Wilhelm Friedrich Hegel (1770–1831) also theorized about knowledge production but wished to push beyond Kant’s separation of mind and self when deconstructing ideologies. Instead, Hegel sought to historicize the process of arriving at truth. Hegel viewed history as progress toward a greater humanity—and Utopia—through a higher consciousness of self in and with the world. Dialectic reasoning is the path to this truth and involves engaging in dialog to overcome the contradictions between thesis and antithesis toward a synthesis.

Following Hegel, Karl Marx’s (1818–83) work with Friedrich Engels regarding the historical and material conditions of capitalism is the most influential in shaping critical theory. Marx explained how the bourgeoisie (ruling class) accumulate wealth through the alienation and exploitation of the proletariat (working class). Capitalist ideologies reinforce false consciousness and maintain power in the hands of the ruling class. Thus, Marx provided the basic idea on which critical theory is constructed: those who have economic power in society also control the cultural superstructure of that society. Marx recognized how production and consumption of media (through language) controlled class consciousness and how, simultaneously, such a tool could also be used against oppressive capitalist ideologies for a better humanity.

The Frankfurt School

The original home of the Frankfurt School was in the Institute for Social Research (Das Institut für Sozial-forschung) that was founded in Frankfurt, Germany, in February 1923, but was forced to move under Nazi threat in 1933. In 1930, the Institute came under the directorship of Max Horkheimer and grew to include critical theorists such as Erich Fromm, Herbert Marcuse, Theodor Adorno, and Walter Benjamin who shifted its theoretical focus from an analysis of bourgeois society’s socioeconomic substructures to bourgeois cultural superstructures. Although primarily influenced by Marxism, the Frankfurt School rejected an orthodox reading of Marx and represented a different form of Marxism than their Bolshevik contemporaries, as they did not envision an inevitable proletariat revolution nor focus solely on economic production. Instead, the Frankfurt School sought to understand the relationship between theory and society through a dialectical framework that also examined the realm of culture “including not only the so-called spiritual contents of science, art, and religion, but also law, ethics, fashion, public opinion, sport, amusement, lifestyle, etc.” (Horkheimer, 1972). Thus, the Frankfurt School became both a representation and critique of Western Marxism.

Central to the Frankfurt School’s articulation of critical theory was its critique of the Enlightenment’s conceptualization of instrumental reason, rationality, and positivism (as explored by diverse thinkers including Saint-Simon, Comte, the Vienna Circle, and others). The Frankfurt School believed there was a breakdown in reason due to a “crisis of science” that reduced the concept of knowledge to a limited scientific method of “description, classification, and generalization of phenomena, with no care to distinguish the unimportant from the essential” that could only be resolved through the creation of “a correct theory of the present social situation” (Horkheimer, 1972). Echoing Nietzsche’s belief that it was not science but the scientific method that proved triumphant during the nineteenth century, the Frankfurt School sought to rescue the world from the basic assumptions of logical positivism—that valued objective observation as the only way to produce truth—by envisioning critical theory as an improved approach to human reasoning, supporting a more self-conscious critique of human action for transformation. The Frankfurt School believed that positivist rationality and its narrow view of science endangered human ability to think critically and subjectively regarding the world—freezing human history behind selected, organized, and fetishized facts in false neutrality, rather than recognizing how natural reality and science relate both to human consciousness and lack of consciousness as well as subjectivity and objectivity. The Frankfurt School articulated how those engaged in using positivist rationality were not necessarily conscious of how such an approach could maintain an oppressive power imbalance or the status quo in work labeled as scientific and thus urged philosophers to consider their positionality as producers of knowledge.

In order to address these problems with logical positivity and Enlightenment rationality, the Frankfurt School formulated a critical theory that first recognized the relationship between individuals and society. In this way, critical theory develops a capacity for meta-theory by acknowledging the cultural–historical positionality of interested, non-neutral parties whose political or social interests affect how they navigate and present knowledge or information. With such a self-critical and self-conscious lens, critical theory engages in dialectical thought that lives within the tension between critique and theoretical reconstruction. As noted by Marcuse (1960), “Dialectical thought starts with the experience that the world is unfree; that is to say, man and nature exist in conditions of alienation, exist as ‘other than they are.’ ... Thought ‘corresponds’ to reality only as it transforms reality by comprehending its contradictory structure.” Dialectical methodologies synthesize philosophy, the social sciences, and radical politics to help illustrate how society, state, economy, culture, and the individual are all related to one another. Thus, critical theory should work toward an improved society devoid of injustice and oppression and “emancipation from slavery” (Horkheimer, 1972) through equal engagement of theory and practice in critical praxis. While the concept of “praxis” dates back to ancient Greek philosophy, in the context of critical theory praxis is the changing of circumstance and human activity (Marx and Engels, 1998) that seeks “to liberate human beings from the circumstances that enslave them” (Horkheimer, 1982: 244).

The Frankfurt School also used critical theory to reject essentializing and hierarchical perspectives of culture that were supported by sociologists and orthodox Marxists of the time. The Frankfurt School rejected definitions of culture as a stagnant, objectified ideology, and instead embraced culture as a dynamic political and economic process in the development of human relationships.

Theodor Adorno (1903–69) explored how major culture industries used popular culture—such as film and radio—to advance the oppressive ideologies of the dominant, capitalist society. Through Adorno’s work, critical theory grew to question the dehumanizing relationship between media culture and its consumers, while simultaneously recognizing the power of using new media literacies against such control. In *One Dimensional Man* (Marcuse, 1964), Herbert Marcuse (1898–1979) critiques industrialism’s oppression of individuals for the maintenance of systems of production. Through this work, Marcuse pushed critical theory to demonstrate how a system of production controls individual consumption. In other work, Marcuse also explain elucidate the purpose of dialectical thought as a connection between thought and action in *Reason and Revolution* (Marcuse, 1960), where he writes how “Thought ‘corresponds’ to reality only as it transforms reality by comprehending its contradictory ... nature ... to break down the self-assurance and self-contentment of common sense, to undermine the sinister confidence in the power and language of facts.” Max Horkheimer’s (1895–1973) work focused primarily on the function of reason within philosophy and the creation of oppressive ideologies in larger society particularly significant during a period in which the Nazis were using evil and dehumanizing methods to manipulate society to engage in the mass murder and torture of Jewish, LGBTQ, and other minoritized people. Horkheimer used critical theory as a tool to fight destructive mass ideologies in a rapidly changing world. Walter Benjamin (1892–1940) engaged in critiques of literary and artistic work—building on aesthetic theory while pushing critical theory to discuss the realm of culture and its historical context. Jürgen Habermas (born in 1929) contributed to critical theory in his development of the theory of communicative reason or communicative rationality through discourse ethics and idea exchange. Horkheimer defines a truly critical theory as one that “has as its object human beings as producers of their own historical form of life” (Horkheimer, 1993: 21). Thus, critical theory gives people the agency to challenge taken-for-granted assumptions through tools such as dialectical reasoning and praxis that promote free-thinking and self-determination for all individuals in society.

Critical theory involves engagement in dialectic and critical praxis toward critical consciousness. Critical consciousness involves thinking about power through the analysis of oppression in the world/society/community, identifying one’s identity and naming their role in oppression and engaging in individual and collective social action toward more just practices and policies (Nieto and McDonough, 2011). From this perspective, oppression often relates to the current function of school and other institutions (e.g., family, criminal justice, health care, places of worship) to reproduce or challenge that oppression and hierarchies based on race, social class, and other demographic categories. Critical consciousness requires socio-cultural-political competencies and practices for educational researchers that include political clarity (Bartolomé, 2004) and critical social consciousness (Grant and Agosto, 2008).

Global critical philosophies

Although critical theory itself was born of a Western and European philosophical history, other influential philosophies have also developed (and often preceded) worldwide that we should recognize as part of the critical theory canon. Some such traditions have borrowed from Western philosophies while others have developed more independently and, while not all such work is recognized by North American and European scholars due to language barriers, racism, and imbalanced power relationships between Western imperialists and scholars of other nations, in this section we aim to bring some of these global critical philosophies to the mainstream of Eurocentric critical thought.

African philosophical tradition is rich and varied, with central and longstanding tenets of communalism, justice, and care informing tenets of critical western philosophers like Marx and Horkheimer by offering a vision for interrogating knowledge, power, and the role of individuals working toward liberation through collective social action (Crawford et al., 2009). A critical approach to understanding a communalistic ethos inextricably connects the individual and the larger community and is extrapolated in African socialism by leaders like Julius Nyerere in Tanzania, Kwame Nkrumah in Ghana, among others (Senghor, 1964). Fu-Kiau (2001) points to myriad examples of traditional African communalistic societies where “[e]verybody felt responsible to everybody else in the community and its neighborhood. When a community member suffered, it was the community as a whole that suffered” (p. 50). This communalistic ethos aligns with Horkheimer’s criteria for critical praxis, including a focus on being: (1) explanatory (how people should organize communities), (2) practical (what individuals do in that community), and (3) normative (traditional mores for equitable distribution of power). The ethos of communalism is well-documented in the customs and proverbs of Africa and her diaspora (Ikuenobe, 2006). For example, the proverbs of the Akan people of Ghana, West Africa, describe the interdependence of the individual and collective members of the community where individualism harms not only the community but the individual who receives the benefit: “Obiako di’wo a, etoa ne yam” (“If one alone eats the honey, it plagues his stomach”) (Danquah, 1968, 195).

However, across the continent agents of European colonialism attacked African communalism and justice. Frantz Fanon (1925–61) was a critical and transformative intellectual in the Algerian resistance to such colonialism experienced under French rule. Believed to be influenced by the 1930s Négritude movement—that rejected French colonial racism and was led by Martinican poet Aimé Césaire, Guianan Léon Damas, and future Senegalese President Léopold Sédar Senghor—Fanon explored how the psychology of oppression and the impact of colonialism affected the mental health of colonized people in works like *A Dying Colonialism* (Fanon, 1959) or *Black Skin, White Masks* (Fanon, 1967). By critiquing the way colonial powers control colonial ideology production and dissemination and how media is used to manipulate colonized people into believing in Western racial hierarchies of language, custom, or skin color, Fanon illustrates how indigenous peoples can deconstruct dominant language and texts toward

ideology change for liberation. Fanon's work highly influenced the revolutionaries of other nations—most notably Fidel Castro in Cuba, Paulo Freire in Brazil, and the Black Panthers in the United States.

Former Teacher, Tanzanian President, and African Nationalist and Socialist, Julius Nyerere argued that in the communalistic society, the “educated know themselves to be an integral part of the nation and recognize the responsibility to give greater service [commensurate with] the greater opportunities they have had” (Nyerere, 1967, p. 28). The ability of the educated to serve “the good” of the community is directly related to the type of education they have received. Education has to liberate both the mind and the body of man. It has to make him more of a human being because he is aware of his potential as a human being, and is in a positive, life-enhancing relationship with himself, his neighbor, and his environment. Education must therefore enable people to throw off the impediments to freedom which restrict their full physical and mental development (Nyerere, 1974, p. 3). Thus, the purpose of critical education is relational and contextual. Education has a duty to liberate where schooling is neither fair nor just and the society does not present youth with equal opportunities to learn and to form positive relationships with self, community, and society.

The communalistic justice and care model of achieving “the good” centers on the critical practice of simultaneously considering the needs of the individual and the community (Ekei, 2001; Ikuenobe, 2006). In fact, Walker et al. (2004), point to a dialectic ethical space where “[T]he delineation of self-care and community care into isolated categories fashions a false dichotomy” (p. 11). Within the African Diaspora, critical theorists use communalism to re-imagine liberation in communities and education practices. W.E.B. DuBois (1868–1963) in his famous work—*The Souls of Black Folk* (DuBois, 1903) explores Black individuals and communities' experience in America. DuBois theorizes about “double consciousness” experienced in the African American who sees herself/himself through the gaze of those who hate people of color, and describes the torment this places on the spirits of all people in a racist society. DuBois recognizes how ideologies of race are formed through dominant languages, but how a critical approach to education could help transcend such oppressive ideologies and lead to social change. Following the Harlem Renaissance and the growth of transformative art and literary works that helped engage humanity in a critique of America's anti-Black social structures and institutions, Carter G. Woodson (1875–1950) published *The Miseducation of the Negro* (Woodson, 1933) which challenged the ways classical education incorporated forms of scientific racism by revising world histories to enforce ideas about the racial inferiority of people of color. By removing African Americans and African peoples from school knowledge regarding history and science, classical education dehumanized African Americans and continued to oppress and mold them to the racist, hierarchical American fabric. Woodson calls for a critical education in which people of color could question the schooling they receive for individual and community liberation. Such works not only influenced innumerable educators, scholars, artists, and activists toward a critique of society for social change as is visible in the work of Frederick Douglass, Langston Hughes, Marcus Garvey, Malcolm X, and the Black Panther Movement—all of whom engaged in challenging how knowledge is produced and used to manipulate truth in a racially hierarchical society.

During the 1980s, other scholars—such as Edward Said and Homi Bhabha—pushed critical theorists to think in new ways by developing studies in colonialism and postcolonialism. Recognizing how Western colonialism maintained its hegemony through the control of knowledge and knowledge production, postcolonial theorists engage critical theory in ways most applicable to the current reality of globalization. Although often associated with postmodern theory in its method under the influence of Jacques Derrida's concepts of deconstruction, Jacques Lacan's psychoanalysis, and Michel Foucault's discourse analysis, postcolonial theory still relates to critical theory in how colonized, indigenous peoples have found an agency in critiquing the oppressive societies in which they live. In *Orientalism* (Said, 1978), Said critiques how the West continues to romanticize Asian and Middle Eastern nations as the archaic and unchanging “other”, while using such false ideologies to justify continued imperialism throughout the Orient. Similarly, in *Nation and Narration* (Bhabha, 1990), Bhabha problematizes how postcolonial countries continue to be treated as one, homogeneous group by their ex-colonizers, with concepts of nationhood narrativized through power imbalances between ex-colonizing nations and their ex-colonial states.

Of course, Latin America and Central American development of new critical theories can be traced through the work of Liberation Theology that united indigenous people with Catholic clergy against the oppressive, racist structures of the European Catholic church, or in the work of Ernesto Ché Guevara—Minister of Education in post-revolution Cuba and organizer of the guerrilla mountain schools—but the most notable development of critical theory in education can be found in the work of Paulo Freire (1921–97). Freire, a former teacher like his Black contemporaries Milton Santos and Abdias Nascimento, form part of a tradition of critical activist scholars that extend Western Critical Theories including Marxism and the Frankfurt School to interrogate oppression and imagine more just urban spaces, popular education, and cultural production (Almada, 2013; Santos, 2000; Silva, 2010). For example, Freire's most famous work—*The Pedagogy of the Oppressed*—explores the ways the educational system proves central to the dehumanizing processes of capitalist and neocolonial societies through banking education that treats students as empty vessels that passively collect the oppressive norms and knowledge of teachers. Freire focused on literacy and literacy education while teaching illiterate adults how to interrogate and deconstruct dominant texts within a racist, classist Brazil. Freire believed in the power of praxis and dialog to push critical thought against oppressive forces that control schooling structures. Critical Black theorists in Brazil like Oliveira and Ferreira (2020) have also drawn on African philosophy in dialog with Latin American philosophies of liberation to create a critical ancestral philosophy that is a communal construct respecting wisdom of elders in their experiences toward liberation and the social good in the community that can guide Afro-Brazilians enacting racial and social justice in education and social movements (Oliveira, 2018).

While critical theory has surely influenced and been influenced by revolutionaries, scholars, and activists throughout East Asia, the continued imbalance of power relationships that maintain hierarchies regarding race, class, color, and language in the Western

world continue to negate and oppress East Asian critical scholarship. From our limited ability to explore what is prioritized in English-language academic sources, important dialog has taken place around the concept of second modernity (Beck, 2008; Beck et al., 1995; Beck and Grande, 2010) and capitalist expansion within the context of Bureaucratic Authoritarian states in locations such as Korea or Japan (See, for example, Han, 1997, 2007, 2009). But without translation and prioritization of Eastern knowledge in Western academia, much is being lost in current explorations of critical theory. Critical theorists should immediately address this issue of exclusion of non-western philosophers.

Returning to the West and to the United States, critical theory has been expanded upon, questioned, and integrated in important ways through critical Feminist Theories, Black Feminist Theory and Critical Race Theory that can powerfully inform qualitative research methodologies. Within Feminist Theories, Feminist Standpoint Theorists (Harding, 1991; Hartsock, 2003) have emphasized the need to produce knowledge grounded within the experiences of those who have undergone collective political struggle and been most marginalized from institutional knowledge creation processes. Thus, starting from the lived experiences of women, for example, can prevent research that separates women from their realities toward developing more relevant understandings of how power is constructed and maintained by patriarchal structures. Black Feminist Theory—rooted in Black Feminism that has existed since the time of slavery in the US—centers Black women’s experiences and perspectives, identifying the primacy of their contributions to our world from unique experiences at the intersections of race, gender, class, and sexual identity. Valuing the intersectionality (Crenshaw, 2017) of Black female identity, critical Black Feminist Theory offers much needed analyses of how patriarchy and white supremacy create the oppressive institutions and contexts within which current society operates (see Collins, 2019). Critical Race Theory—building off of early 1980s critical legal studies that centered race in its analyses of law and institutional structures—and LatCrit Theory allow us to examine and challenge the epistemological and methodological foundations of educational research as well as analyze educational institutions and practices through the lens of race and racism (see Solorzano and Yosso, 2000; Solorzano and Bernal, 2001). CRT advances storytelling and counter-storytelling as important qualitative methodologies with which to explore issues of white supremacy, power, and oppression (Solorzano and Yosso, 2001).

Critical theory in qualitative educational research

In qualitative educational research, critical praxis is the reassertion of research design, implementation, and distribution for a more human world at the individual and social levels, where the simultaneous changing of circumstances and self-change occur through self-reflection, reflective action, and collective reflective action (Freire, 1970). Critical qualitative education researchers enact critical praxis to support students through the co-construction of educational practices that allow people to acquire, analyze, and produce both social and self-knowledge (Ryoo et al., 2009).

What makes research “critical”?

Critical theorists who conduct qualitative research in education share similar ways of knowing and challenging inequitable distribution of power and privileged or marginalized ways of being within social relations. Marx (1969), in his 11th Thesis on Feuerbach reminds us of the epistemological and ontological telos of a critical knowledge production is political action, “Philosophers have hitherto only interpreted the world in various ways; the point is to change it.” This statement reflects the shared value that critical theorists conducting qualitative research share of critique of oppression indexed in current social relations and transformative social actions. While the type and amount of change depends on a critical theorist’s orientation, all educational researchers employing critical theory concur that research, knowledge production, and educational practices are political (Chun and Morgan, 2019). Zinn (2018) popularized this position when he said that, “you can’t be neutral on a moving train.” If a qualitative researcher is not actively contesting oppression through anti-racist and anti-capitalist research practices, then they are perpetuating white supremacy and economic exploitation. All phases of qualitative research design, data collection and analysis, and knowledge dissemination benefit from critical consciousness and critical praxis (Kincheloe and McLaren, 2011). To transform systems, critical theorists in qualitative education research engage in iterative processes of critical consciousness and critical praxis (as described above).

Contemporary critical accounts of schools in the United States

Given the current structure of public primary and secondary schools in the United States, a commodification of learning and the learner often occurs when educational researchers function as dutiful knowledge producers carrying out mandates generated from the dominant elite and their funding sources with little input from stakeholders in schools (Kincheloe and McLaren, 2011; McLaren and Giarelli, 1995). These mandates include implementing scripted-curricula in overcrowded classrooms and administering high-stakes assessments and zero tolerance discipline policies that bolster opportunity gaps and cause students to be compliant “objects” during the learning process (Apple, 2004). Not coincidentally, these educational practices are widely supported by money interests and the state (Marx, 2019; see also Marx, 1972).

Lave and McDermott (2002) illustrate further that, “Just as the result of alienated labor is embodied in the things produced, so the object of alienated learning becomes material in the things learned The learner becomes all the poorer the more he becomes subject to the whim of the educational system” (p. 34). In this way the object of alienated research becomes material in the

knowledge produced, whereas the researcher becomes poorer the more they are subject to conducting research that does not support critical consciousness or praxis that challenges scripted curricula and standardized assessments and a host of other institutional practices that support the status quo of racial and class oppression in schools.

However, there is a long history of activists and critical researchers who have been able to negotiate structural and institutional constraints in schools through their writing and research while bringing about radical changes in society (Woodson, 1933; DuBois, 1903; Douglass, 2018). Critical educational researchers recognize how traditional schooling works against the interests of those students who are most vulnerable in society by reproducing class differences and racialized inequality (McLaren, 2006; Giroux, 1983; Shor, 1992; Darder, 2011). Critical qualitative educational researchers are committed to creating an emancipatory culture of schooling that counters alienation. Through critical consciousness and praxis, critical qualitative researchers aim to resolve the tensions inherent in researching schooling against the status quo amid educational and research institutions that support it.

Applications of critical theory in qualitative educational research

Kincheloe and McLaren (2011) argue that the application of critical theory in qualitative educational research centers on a transformative praxis that works to understand and alleviate oppression. Critical qualitative educational researchers move beyond empirical descriptions of “what is?” to ask, “how what is has come to be, whose interests are served by particular institutional arrangements, and where our own frames of reference come from” in order to enact “critical world making” with others (p. 315). While an exhaustive review of all educational qualitative research that interrogates injustice and aims toward transformative praxis is beyond this brief chapter, in this section we will review key methodological approaches and examples of qualitative education studies informed by critical theory in the United States. These methods grow from critical ethnography and include duoethnography, counter-storytelling, and participatory action research.

Critical ethnography

Beginning in the 1930s, community sociologists and in the 1960s action anthropologists contributed to critiques of racial and class inequalities with research narratives of oppressed communities that were more asset-based rather than deficit oriented (Vidich and Lyman, 2000). One contemporary design sociologist, Hugh Mehan, extended critiques of inequity in public education to action by co-creating a public school based on equitable policies (like detracking and community engagement) and rigorous and inclusive teaching (Mehan, 2008). More recent activist anthropologists expand collaborative research design and execution with multimodal mediums of dissemination of their studies (Foley and Valenzuela, 2004; see special issue of the *Anthropology and Education Quarterly* 2008). This approach was used by Bowles and Gintis (1976) in their seminal study of the social reproductive function of school for working class students and by Valenzuela (1999) to look at the way high school assimilation policies and practices takes away US–Mexican youths social capital in a public high school. Three examples of specific approaches aligned with a critical theory that follow the basic tenets of critical ethnography are duoethnography, counter story-telling, and participatory action research.

Duoethnography

Duoethnographers enact social justice by examining power, privilege and improving conditions of teaching and learning. The process of duoethnography involves the following six iterative steps: (1) select a phenomenon, (2) analyze the phenomenon, (3) engage in abduction (explanatory reasoning), (4) situate the data, (5) critique that data, (6) develop an insight (Sawyer and Norris, 2013). Researchers analyze themselves as text in context in a recursive process grounded in trust and a commitment to question emergent common understandings through a dialog. This approach was used by Diversi and Moreira (2009) who worked with street children in Brazil, Sawyer and Liggett (2016) who explored postcolonial education, Koonce and Lewis (2020) who explored critical care in their university classrooms, and McDermott et al. (2012) who interrogated a curriculum of beauty. These approaches align with the telos of critical theory with explicit emphasis on praxis through a collective reflective action, or what Freire (1970) calls conscientization and Pinar (1975) describes as *currere*. This process calls for critical self-analysis and unlearning of internalized colonial, neocolonial, neoliberal and other oppressive discourses and narratives toward what Said (1993) calls the counterpunctual narrative in order to find a “new way to imagine cultural worlds with the tension of standardized and often neoliberal discourses” (Sawyer and Norris, 2013, p. 8).

Counter story-telling

Many critical race theorists conduct qualitative education research using counter story-telling. This approach to research draws on Critical Race Theory to unmask racialized experiences by showing how race organizes non-racial phenomena, policies, practices, and interactions. Researchers using counter story-telling methods begin with the assumption that race is a narrative with social and material consequences. Narrative has been important in constructing and deconstructing white supremacy throughout the history of the United States (Baszile, 2015) and is also particularly important to indigenous epistemologies (Brayboy, 2005). Race stories construct our actions and beliefs. The practice of counter storytelling reconstructs narratives from the views of the oppressed to arrive at a more complete understanding of oppression and social change (Solórzano and Yosso, 2002).

Counter story-telling studies have been used to study race and racism in education from the point of view of Black students (DeCuir and Dixon, 2004; Howard, 2008), students engaged in action research (Goessling, 2018; Hauber-Özer et al., 2021), parents and families of Black children in public schools (Lewis and Adkins-Sharif, 2020; Reynolds, 2010), Black K-12 teachers (Cook and Dixon, 2013) and school leaders (Parker and Villalpando, 2007), Latinx graduate students (Solórzano and Yosso, 2001), and Black

university faculty (Griffin et al., 2014). For example, Howard (2008) analyzed Black male's stories of their schooling experiences of teachers and school administrator's racialized and deficit perceptions of them and how they worked to "eradicate negative racial stereotypes" of Black males in schools (p. 954). Croom and Marsh (2016) share studies from university faculty and administrators who use counter storytelling to enact greater justice in school policies, labor practices, academic curriculum, and classroom pedagogy. These myriad counter story-telling qualitative studies across educational contexts share a commitment to Black educational officials, learners, and community to name their own reality, challenge individual and institutional racism, and re-imagine more racially just schools.

Participatory action research

Conducting qualitative educational research through critical inquiry to liberate learners and transform schools is central to participatory action research (PAR) designs (Kemmis et al., 2013). Participatory action research with a critical lens involves educators examining their own practice in collaboration with their students to question and interrogate structural issues of power and the inequitable distribution of social and material resources through solidarity work (Martínez-Roldán and Quiñones, 2016; Martinez, 2017).

One example of an emerging trend aligned with critical theory under the umbrella of PAR is Youth Participatory Action Research (YPAR) (Mirra et al., 2015). Critical qualitative researchers have explored YPAR as approaches to a pedagogy of resistance (Camarota and Fine, 2010), multicultural education (Irizarry, 2009), service learning (Schensul and Berg, 2004), civic engagement and advocacy (Kirshner, 2010), and policy-making (Warren and Marciano, 2018). A systematic review of 63 YPAR studies found that most youth who participated in these studies gained agency and leadership, as well as academic or career skills (Anyon et al., 2018). For example, Akom et al. (2016) describe how young researchers in Oakland, California used digital technology with local community members that "sparked a food revolution" by identifying food insecurity and working with schools and community leaders and organizations to improve access to healthy food in their neighborhood. These studies share the fact that they are community-based and involve youth in identifying and acting on social, economic, cultural and political issues with a goal of more just access, representation, experience, and policies.

Conclusion

Here we have explored the history and key ideas of critical theory, as well as its application to education and qualitative educational research. Critical theory in qualitative research supports the interrogation of oppression, the analysis of power structures, and ultimately an engagement in social action toward creating more just learning contexts and communities. Qualitative educational researchers apply critical theory through interrogating (a dialogical reasoning of) the relationship between ways of knowing and being, oppressive schooling and educational practices, and unjust social relations in schools and other social institutions. Critical qualitative educational researchers critique exploitation in schools and work collectively to assert teachers', students' and communities' humanity through research that often includes social action. As the field continues to grow, critical qualitative educational researchers in the United States should prioritize Africa, Asian, and Latin America (among other) critical philosophies, research methods and general approaches to knowledge production. Qualitative educational researchers applying critical theories will continue to strive for solidarity with local and global communities of researchers, educators and learners to critique exploitation and humanize classrooms, schools, and societies.

Introduction

While qualitative research that centers gender in education can be conducted using commonly-used paradigms, including postpositivist, social constructivist, and pragmatic paradigms, much of those approaches are conducted without regard to existing power dynamics or concern for liberatory or emancipatory aims for participants (Creswell and Plano Clark, 2017; Hurtado, 2015). This chapter focuses on those methodologies guided by transformative paradigmatic approaches that hold potential for the researcher to become an “instrument of social change” (Merten, 2009, p. 11), empowering marginalized communities and seeking social justice as a key aim for participants. Influenced by social and intellectual movements, researchers became frustrated with existing paradigms and research methods that ignored or obscured the power dimensions that influence the lives of participants and their contexts, which privileged researchers’ epistemologies while undervaluing participants’ voice, active resistance, and agency.

With a focus on the perspectives of scholars conducting research with underserved and marginalized communities, this chapter illuminates how critical and feminist theories and methodologies enrich qualitative education research. Because feminist research approaches are comprehensively captured in other volumes (Hesse-Biber, 2007, 2014), we offer a brief overview of feminist research within the context of critical social theories and provide select examples that demonstrate how critical and feminist theories and methodologies are used in education research. Next, we share personal researcher accounts on conducting qualitative research in education with gender identity and intersections with racial/ethnic groups. We particularly focus on the roles of positionality and reflexivity as insights into the complexities and possibilities to advance a social justice agenda and perform transformative educational research. In doing so, we provide insights into how conducting gender identity research in education can also be transformative for researchers as they become more conscious of their role in relation to marginalized communities.

Adopting a transformative paradigm

Recognizing the persistent educational and societal inequities, Rios-Aguilar and Neri (2021) call for “educational research that contributes to revitalized critique and transformative pro-action against educational reproduction of existing inequalities” (p. 2). In working toward proactive solutions, the key elements of the transformative approach indicate a concern for social justice and the welfare of marginalized communities that permeate the entire research process. The transformative paradigm is a “metaphysical” umbrella and framework for basic beliefs, epistemologies, and research practices that recognize marginalized identities and are guided by critical theory, feminist theory, critical race theory, queer theory, decolonial, and culturally responsive approaches (Merton, 2009, p. 13). It is guided by ethical concerns that show respect for cultural norms and conditions, rejects deficit assumptions, and identifies participants’ strengths and critical resilience. Researchers working in this paradigm recognize the co-existence of multiple realities shaped by social, political, gender, racial, and economic contexts and conditions that reveal unequal power relationships. They recognize epistemological differences and similarities that shape their role in relation to participants, requiring the development of a trusting relationship. Merten (2009) indicates that the transformative paradigm requires qualitative methods (although mixed methods can also be used) to address cultural complexity. Using qualitative methods with a critical perspective

also accounts for contexts and histories that involve multiple forms of oppression, remaining cognizant of dominant perspectives that permeate methods and decisions that can adversely affect participants and social justice aims.

Advancing a transformative paradigm requires the use of approaches that challenge dominant ideologies and traditional ways and methods of knowing. Critical social theories employ culturally situated frameworks and intentionally address systems of oppression and power. The interrogation of power and subordination is not only reflected in critiques of the social organization of society but also in knowledge structures. Cynthia Dillard (2000) explains that the construction of knowledge is not neutral, “all research is social construction and a cultural endeavor,” (p. 662) in which she underscores how research is shaped by and shapes ideologies. For example, ideologies such as whiteness, racism, and patriarchy are rendered normative and permeate traditional approaches to research (Allen et al., 2019; Bhattacharya, 2019; Evans-Winters and Esposito, 2019; García and Mayorga, 2018; Gillborn, 2010; Harding, 1987; Zuberi and Bonilla-Silva, 2008). Bhattacharya (2019) contends that the overwhelming representation of white faculty who teach qualitative research and the subsequent lack of qualitative methods training that interrogates whiteness demonstrates how “qualitative research is mostly celebrated through a form of whiteness” that itself “cannot generate any knowledge that is completely devoid of whiteness” (p. 113). Thus, while qualitative research is typically intended to be sensitive to participants’ experiences, traditionally accepted modes of knowledge production are inextricable from whiteness, patriarchy, and other forms of domination.

Disrupting dominant ideologies in qualitative research

The perpetuation of dominant ideologies in traditional qualitative research approaches and training (re)produces systems of subjugation and inequity. Fundamentally, research is a mechanism to create and disseminate knowledge that can shape social life, including influencing or hindering life opportunities. Such a process necessitates the transformation of the procedures entailed in research inquiry to disrupt the colonial norms of white supremacy, heteropatriarchy, and other intersecting systems of domination imbued within research practices (Dillard, 2000; Evans-Winters and Esposito, 2019; Smith, 2012). The role of ideology in research calls for attention to research practices, which include what is represented as knowledge, the process of knowledge production, and who is authorized to be bearers and producers of knowledge.

Critical social theories and frameworks emphasize how ontological and epistemological orientations inform theory, as well as methodology, methods, and analysis. Examples of critical social theories, frameworks, and methodologies that are attentive to oppressive social structures and/or empowerment for minoritized groups include community cultural wealth (Yosso, 2005), critical race theory in education (Gillborn and Ladson-Billings, 2010; Ladson-Billings and Tate, 1995; Lynn and Dixon, 2021; Patton, 2016; Solórzano, 1997), decolonizing and anticolonial methodologies (Bhattacharya, 2019; Patel, 2014; Smith, 2012), funds of knowledge (Kiyama and Rios-Aguilar, 2017), funds of identity (Esteban-Guitart, 2016), racial capitalism (Robinson, 2020), and racial formation theory (Omi and Winant, 2014). Though varied in ontological histories, epistemic standpoints, and approaches, a feminist inquiry is another example of research that critiques oppressive social structures and seeks the empowerment of participants (Collins, 2000; Harding, 1987; Naples and Gurr, 2014).

Feminist theories and methodologies have the potential to transform education research and praxis. “Feminist research positions gender as the categorical center of inquiry and the research process,” in which “feminist researchers use gender as a lens through which to focus on social issues” (Hesse-Biber, 2014, p. 3). While some employments of feminist thought solely center on the experiences of cisgender women through the inappropriate equation of biological sex and gender identity, such as trans exclusionary radical feminism (Gutzwa, 2021a), feminist research does not inherently reinforce narrow categorizations and conceptions of biological differences. Instead, Feminists of Color, such as Black Feminist Cynthia Dillard (2000), extend researchers’ and participants’ ontology and epistemology as grounded in community:

When we begin to move beyond race/ethnicity and gender as biological constructions to more culturally engaged explanations of being human, and when we seek to examine the origins of such knowledge constructions as to the very nature of how reality is known (its patterns of epistemology), we will find that what constitutes knowledge depends profoundly on the consensus and ethos of the community in which it is grounded (p. 661–662).

Similarly, Evans-Winters and Esposito (2019) explain how critical race feminist frameworks such as intersectionality are useful in critiquing social order and hierarchy:

It is through a shared understanding of the social world that women of color, the indigenous, racial and ethnic minoritized people, queer and non-gender conforming people, and the poor, especially, can draw upon intersectionality as an analytical tool in the examination of (and resistance to) systems of power, privilege, and domination. (p. 56)

Feminist research is a mode of analysis to identify and challenge the ways that hegemonic, patriarchal systems of domination impact communities broadly. Feminists of Color point out that this challenge of pervasive patriarchal violence also critiques how reliance on narratives of whiteness excludes the realities of Black, Indigenous, and other People of Color (Lorde, 1984a). For example, Dillard (2000) contends that endarkened feminists engage in a “social critique” that “is focused on the violence

perpetrated in the universal generalization from the particular White male knowledge of the nature of reality to describe everyone's realities" (p. 671).

As such, the use of gender as a category necessitates nuance given people's diverse worldviews and varied social positions shaped by social contexts and power structures (Collins, 2019a). Across methodological approaches, such nuance is falsely viewed as difficult to actualize, as white, cisgender, heterosexual scholars often forego the intentionality required in discussing minoritized identities when whiteness is no longer a normative focal point of discourse. In quantitative research, using gender as a categorical variable can potentially essentialize the status of a gendered group because measures and statistical analyses may not have the explanatory power to consider exogenous factors that qualitative approaches can explore (Catalano, 2017; McLewis, 2021; Patton et al., 2016). For example, research on gender differences that compare groups at the aggregate level presumes a universal lived experience driven by one's social identity. Even within qualitative research, essentialist notions of gender can be reinforced when scholars do not consider the variation in lived experiences across and within gendered groups (Patton and Njoku, 2019; Stewart, 2022).

Moreover, viewing all feminist research through the reductionist perspective of feminism as an inquiry into cisgender women's issues succumbs to hegemonic descriptors of gender binaries, namely cisgender women and men. In articulating the uses of feminist frameworks in qualitative research, Creswell and Creswell (2018) simplify the focus of this work as women in context: "Feminist perspectives view as problematic women's diverse situations and the institutions that frame those situations. Research topics may include policy issues related to realizing social justice for women in specific contexts or knowledge about oppressive situations for women" (p. 62). This philosophical assumption implies that the utility of feminist frameworks is limited to exploring the experiences of cisgender women. Reducing feminist research on social issues related to women discounts the complexity and evolving conceptions of gender and erases the experiences of sexually minoritized groups (Nicolazzo, 2019; Stewart, 2022), which is ultimately antithetical to the advancement of a transformative paradigm. The oversimplification of feminist research as the study of women's issues also dismisses how a gendered lens can enrich inquiry on social dilemmas and inequities that fortify marginalization and domination. For instance, a gendered lens and/or feminist frameworks may be used to examine men, masculinity, and power relations (Okello, 2019); similarly, when theorized in ways that affirm the socially constructed nature of gender as an identity category, feminist frameworks are well-suited to explore the lived realities of those who hold gender identities beyond the cisgender binary (Carrera-Fernández and DePalma, 2020). In what follows, we discuss how utilizing expansive approaches to feminist epistemologies and theories can effectively center minoritized groups in qualitative inquiry.

Feminist epistemologies and theories

In centering the perspectives of minoritized groups in critical social and feminist research, entry into interrogating ways of knowing in education research reckons with the fraught history of white supremacy and settler colonialism that has prioritized white-dominant social constructions of gender that have historically excluded and exploited Black, Indigenous, and other People of Color (Arvin et al., 2013; Smith, 2012). For example, though intersectionality is now popularized in academic research, Black women have long undertaken an intersectional analysis in intellectual and social justice projects:

Before critical legal scholar and Black feminist Kimberlé Crenshaw coined the term that emerged in academic and legal discourse as intersectionality in the late 1980s (Collins 2019a), Black women were describing and documenting how the intersection of race, gender, class, and sexuality shaped their treatment in US society. In 1861, Harriet Ann Jacobs introduced the enslaved Black woman as the subject while exposing the ills of American slavery in *Incidents in the Life of a Slave Girl*. Early narratives and writings of scholars and activists like Sojourner Truth, Maria Stewart, Anna Julia Cooper, Ida B. Wells, Mary Church Terrell, Frances Beal, and Angela Davis also addressed the structural oppression of Black women.

McLewis (2021), p.136.

Thus, Black Feminists have drawn upon the lessons and knowledge produced by Black women that are rendered unorthodox and not historically welcomed in academia or mainstream white feminist traditions.

Centering women of color feminisms

The feminist identification has been interrogated, contested, and even refuted because of the history of marginalizing racial, working-class, queer, transgender, and non-conforming gender identities and their prioritization of concerns regarding cis-white feminist social movements organizations and research (Evans-Winters, 2019; Moraga and Anzaldúa, 1983). For example, the Combahee River Collective, a collective of Black feminist activists, was formed in 1974, because of their status and experiences of being Black lesbians and socialists marginalized in feminist and civil rights movements. The Combahee River Collective called for the "development of integrated analysis and practice based upon the fact that the major systems of oppression are interlocking" (Hull et al., 1982, p. 13). Similarly, within the research and scholarly communities, minoritized groups have challenged the marginalizing structure of traditional approaches to feminist theory.

Faced with simultaneously being suppressed within feminist research traditions and their respective academic disciplines and fields, Women of Color sought their own cultural epistemologies and standpoints to develop theories, frameworks, and praxis that advanced liberatory practices (Arvin et al., 2013; Crenshaw, 1989; Dill and Kohlman, 2012; Guy-Sheftall, 1995). For example,

intersectionality as a social justice project (Collins, 2019b), analytical framework (Harris and Patton, 2018; Núñez, 2014), and method (Evans-Winters and Esposito, 2019; Museus and Griffin, 2011) advance an analytic that accounts for the nuanced ways people holding multiple, intersecting minoritized identities experience systemic domination structurally, politically, and representationally (Crenshaw, 1989, 1991). Other examples include Critical Race Feminism in legal studies, though now also used in education research (Wing, 2003), and Black Feminist Sociology (Brewer, 1989; Luna and Pirtle, 2021). Within the field of education, Scholars of Color have employed interdisciplinary and critical approaches to advance feminist epistemologies and theories that are attentive to how gender interlocks with other social identities in education contexts. For instance, Delgado Bernal (1998) contends Chicana Feminist Epistemology in education is a “means to resist epistemological racism and to recover untold histories” (p. 556). Among Black feminist theorists, Cynthia Dillard (Dillard, 2000) offers endarkened feminist epistemology which posits

Reality is known when based in the historical roots of Black feminist thought, embodying a distinguishable difference in cultural standpoint, located in the intersection/overlap of the culturally constructed socializations of race, gender, and other identities and the historical and contemporary contexts of oppressions and resistance for African-American women. (p. 662)

Native feminist theory calls for the need to engage with settler colonialism which is too routinely omitted in race and gender discourses (Arvin et al., 2013). Native feminist theorists

actively seek alliances in which differences are respected and issues of land and tribal belonging are not erased in order to create solidarity, but rather, relationships to settler colonialism are acknowledged as issues that are critical to social justice and political work that must be addressed.

Arvin et al. (2013), p.19.

These examples are a select few approaches to feminist theory in education research and are by no means an exhaustive list or fully capture the ontological history and breadth of diverse thoughts and practices within each.

The role of feminist and critical social theories

Critical social and feminist theory account for how epistemology and ontology provide a worldview that informs the research process, including the framing of research questions, the data collection process, the intentionality in data analysis and dissemination, and the justification and contributions for the inquiry. Venus Evans-Winters (2019) describes Black feminism as a mosaic that enriches qualitative research. “Black feminist scholars bring a wealth of knowledge, skills, talents, and experiences into the research process. These bits of experiences mold together to construct our multiple identities. And, from these multiple identities, yields a creative, distinctly mosaic worldview” (p. 15). Education researchers have employed Women of Color feminism and epistemologies to disrupt the race and gender neutrality that permeates scholarship. For example, McLewis (2021) applied Collins (2000) matrix of domination to challenge traditional approaches to studying college “choice.” Others have used Women of Color feminism and epistemologies to develop new theories and frameworks such as Black Girl Cartography (Butler, 2018) and Chicana Motherwork (Caballero et al., 2019) to defy mainstream knowledge structures.

Subsets of feminist theories have also long been inclusive of queer and trans identities. Foundational Black and Chicana feminists, such as Audre Lorde and Gloria Anzaldúa, centered their queer identities in their theorization, carving feminist inquiry as a space to explore the ways queerness intersects with race and gender. Queer scholars of color similarly draw on the work of Women of Color feminisms in constructing critical frameworks that speak to intersections of identities. Brockenbrough (2015), for example, draws from Black feminist scholarship (namely intersectionality) in adapting a Queer of Color critique to educational research. Similarly, at the intersection of race, gender, and sexuality, the critical framework of Jotería Studies is a theoretical framework to examine the experiences of queer Latinx students (Duran et al., 2020). The work of Transfeminists of Color, such as Koyama (2003, 2020), has been employed in education scholarship to demonstrate the ways “schools are rife with gender category oppression and gender transgression oppression” and argue that “teacher educators prepare teachers to challenge the gender oppression matrix in their classrooms” (Rands, 2009, p. 423).

Beyond feminist paradigms, other critical frameworks have been employed to explore the lived realities of both queer and transgender, nonbinary, and gender-nonconforming communities in education research. For one, queer theory has become increasingly commonplace in higher education research centering queer communities (Renn, 2010) and in student affairs research and praxis (Kasch, 2013). Queer theory allows “a critique of societal constructs surrounding sexuality and gender, namely how these constructs determine what is deemed normal” (Goodman and Garcia, 2021, p. 4), discourses that have historically been utilized to police stakeholders at a variety of levels in education and across various educational sectors (Renn, 2010). Scholars have employed more traditional understandings of queer theory in the exploration of queer and trans student experiences across educational sectors (e.g., Abes and Kasch, 2007; Schmidt, 2017), as well as frameworks that advance queer theory to accurately reflect the realities of queer Communities of Color, particularly Black, Indigenous, and other trans People of Color. For example, Queer of Color critique has emerged in education research to critically center queer and trans people of color (QTPOC) narratives in K-12 (Brockenbrough, 2015) and postsecondary education scholarship, such as Duran and Garcia’s (2021) exploration of how Queer Women of Color in

culturally-based sororities experience communal inclusion and exclusion in social media. Critical trans politics, which emerged from the legal scholarship of Dean Spade (2015) and draws from both Women of Color feminisms and queer theory, has similarly informed scholarship centering on the experiences of trans students (Nicolazzo, 2017) and faculty (Jourian et al., 2015) in higher education. Community cultural wealth has also been used as a critical framework in scholarship centering queer and trans-Latinx communities in postsecondary education, such as Duran and Pérez II's (2018) work on how chosen *familia* develops and strengthens queer Latino men's various forms of capital.

Aforementioned are select examples of critical social and feminist theories that can be utilized in qualitative research to illuminate and respond to the concerns of minoritized groups that are often erased from "traditional" ways of knowing. We offer these examples to demonstrate the boundless potential of critical social and feminist theory in transforming qualitative inquiry. In the next section, we argue the importance of infusing critical approaches such as these into all stages of qualitative research design and data collection.

Methodology, methods, and analysis

Fundamental in critical social and feminist theories is that research is culturally situated. Considerations on how methodology and methods are carried out that affirm both the researcher and participant as knowledge producers are central. Scholars oftentimes interchange the terms "methodology" and "methods" (Mackenzie and Knipe, 2006); as such, we begin this section by offering concrete definitions of both research methodologies and methods offered by Harding (1987) to highlight the nuances between these concepts.

Methodology is "a theory and analysis of how research does or should proceed" (Harding, 1987, p. 3). Methodologies are conceptualized as research strategies of inquiry that are connected to the epistemologies, theories, and methods a researcher employs by their research design (Denzin and Lincoln, 2005). These strategies of inquiry "comprise a bundle of skills, assumptions, and practices" that shape how the researcher navigates "from paradigm to the empirical world" (Denzin and Lincoln, 2005, p. 25). Though often conflated with various aspects of the research process, methods as a term is used to describe "a technique for (or way of proceeding in) gathering evidence" (Harding, 1987, p. 2). Further integral to the research design process is data analysis and interpretation. In this section, we explore modalities employed by feminist and critical social theorists to integrate theory and method in qualitative research.

Methodologies

Within the field of education, critical and feminist scholars use various methodologies and methods to examine gender in education research. While some scholars have used more traditional qualitative inquiry approaches (Creswell and Creswell, 2018), these research strategies have their own histories, approaches, and canonical texts rooted in the white cisheteropatriarchy, ideologies that are not in alignment with existing and burgeoning social issues and concerns (Denzin and Lincoln, 2005). Critics have revamped research designs that encompass critical perspectives (i.e., critical race grounded theory, endarkened narrative inquiry, feminist ethnography, queer phenomenology). Some scholars have even innovated alternative methodological approaches that characteristically reimagine research inquiry, such as Okello's (2019) Black feminist performance auto/ethnographic approach or Johnson's (2015) *sista* circle methodology.

Such transformative work proposes alternatives to white male and cisgender orientations of knowledge production that are accustomed practices that are culturally familiar to researchers and/or participants and communities. For People of Color, and/or queer, trans, and other minoritized scholars, this often requires decentering disciplinary standards of the research process. As Bhattacharya (2019) contends, "if we accept that qualitative research is a colonizing enterprise, then we must actively construct new approaches to inquiry that are consistent with our ontoepistemic orientation and that honor the communities with whom we work" (p. 114). This involves rigorously engaging with robust modes of knowledge production, analytical practices, and methodological sensibilities that are attuned to other ways of knowing and being that may be cultural, indigenous, ancestral, spiritual, or activist.

Methods

Further, pushing against research boundaries and refuting research standards reinforced in positivist paradigms, critical social theorists invite methods and tools that disrupt how we conceive what is research data, what is considered means for data collection, and approaches to engaging research participants and communities. As defined above, research methods describe the specific tools used by the researcher to proceed in data collection (Harding, 1987). Methods can include augmented fotonovelas (Hidalgo, 2015), counternarratives and counterstories (Jones, 2021), native texts (Sabzalian (2016), photovoice (Phelps-Ward et al., 2021), *platicas* (Flores and Morales, 2021), poetic elicitation of identities (Gutzwa, 2021b, 2022), portraiture (Dixon et al., 2005; Lawrence-Lightfoot and Davis, 1997), *sista* circles (Brown et al., 2021; Johnson, 2015; Palmer, 2021), storytelling (Toliver, 2021), testimonios (Delgado Bernal et al., 2012; Huber, 2009), walking interviews (Harris, 2019), writings (Muhammad, 2012), and the use of zines (Honma, 2016) to amplify unheard voices.

Researchers employ these methodological techniques that are responsive to the historical, geographical, social, cultural, and political contexts that shape participants' lived experiences and encourage their expression of resistance. For example, critical race feminists use counterstories or counternarratives to challenge the power relations that uphold dominant forms of knowledge. This acknowledges and legitimizes minoritized communities' epistemologies, as not all ways of knowing are equally valued in research or societal contexts. For example, [Jones \(2021\)](#) uses counterstorytelling to examine how Black women negotiate gendered racial microaggressions at historically white postsecondary institutions. Another example is the use of testimonios, both a methodology and method grounded in feminist tradition as a "pedagogical, methodological, and activist approach to social justice that transgresses traditional paradigms in academia" and "challenges objectivity by situating the individual in communion with a collective experience marked by marginalization, oppression, or resistance" ([Delgado Bernal et al., 2012](#), p. 363).

Data analysis and interpretation

At their core, interpretations of qualitative data are "constructive," "endlessly creative and interpretive," and stem from analytic processes that are "both artistic and political" ([Denzin and Lincoln, 2005](#), p. 26). Although feminist and critical social approaches to data collection are plentiful, guides for feminist and critical analysis of qualitative data are notably more elusive ([Bhattacharya, 2019](#); [Maynard, 2004](#)). This may be because there is no one prescribed form of data analysis that is specific to feminist theory; instead, feminist perspectives are employed in the data analysis process to encompass how researchers make meaning of social life in relation to gender, power hierarchies, and systems of domination. Researchers are often implored to marry their theories and epistemologies with every element of research design ([Grant and Osanloo, 2014](#)), however most methodologists discuss the importance of intertwining theory and analysis without instructing on how to effectively do so (e.g., [Saldaña, 2020](#)) or discuss the importance of data analysis in generating future theory. In this section, we work to offer guidance on the integration of critical social and feminist theories with data analysis.

Data analysis encompasses what [Miles et al. \(2020\)](#) refer to as "three concurrent flows of activity: data condensation, data display, and conclusion drawing/verification" (p. 8). Qualitative data analysis comprises of several traditionally accepted strategies, ranging from jottings and reflective memoing ([Saldaña, 2020](#)) to coding ([Saldaña, 2015](#)) and member checking ([Birt et al., 2016](#)), that are ideally intentionally selected by the researcher: "qualitative research methods have theoretical underpinnings that guide the study with emphasis on the development of a theory a posteriori during the data analysis phase" ([Grant and Osanloo, 2014](#), p. 21). For example, qualitative scholars guided by Black feminist epistemologies strive to construct their data analysis in ways that honor the ideals of reflexivity, identity salience, and self-authorship which Black feminism prioritizes, such as by adopting in vivo or open coding strategies that honor the self-authored narratives of participants ([Clemons, 2019](#)). Integrating participants as co-researchers in the analysis process is another way Black feminist scholars have worked to critically transform data analysis, with [Evans-Winters \(2019, p. 5\)](#) offering an understanding of qualitative data analysis as "a co-constructed piece of artwork" between her and her participants (p. 5). Similarly, researchers guided by Black queer studies, such as epistemologies of BlackLove, strive to prioritize relationality, communal solidarity, and ancestral legacies ([McGuire et al., 2022](#)).

These examples highlight feminist and critical social epistemologies as powerful tools that can reject white, cisheteronormative, patriarchal understandings of knowledge production traditionally prioritized by qualitative research ([Bhattacharya, 2019](#); [Robinson, 2022](#)). As such, while coding and member checking are some of the analytic tools available to qualitative researchers, those guided by feminist and critical social theories must also consider expanding beyond those strategies of data analysis that are reified as "rigorous." [Robinson \(2022\)](#), for example, offers their understanding of non-binary knowledge production as an epistemology that "captures my state of thinking about my own experiences of marginalization and discrimination and a way that exposes and disrupts cisheteronormative and heteronormative ways of knowing and writing" (p. 3); in doing so, they suggest that writing and theorizing about silencing in one's lived experiences is one potential analytic tool that can challenge the hegemonic prioritization of disclosure in qualitative inquiry.

Such strategies that connect the personhood of a researcher, the participants they are in community with, and the epistemologies they employ can be adopted by all: as [Robinson \(2022\)](#) reminds, "if they experience gender recognition, they too can theorize what this recognition means in relation to their field sites, methods, and the people in their study" (p. 15). Thoughtful interrogation of both positionality and reflexivity is therefore a vital component of feminist and critical social approaches to data analysis, as the "complex, messy, and multilayered" approaches researchers take in interpreting data reflect the complexities and nuances across their in/visible social identities ([Evans-Winters and Esposito, 2019](#), p. 55). In the next section, we discuss the importance of positionality and reflexivity in feminist and other critical social qualitative research, providing examples of positionality in praxis as reflections of the ways we as authors have individually engaged our shifting and evolving positionalities in our work.

Positionality and reflexivity

Critical and feminist approaches to qualitative research contend knowledge is socially constructed and dependent on the perspectives that are being privileged ([Collins, 2019b](#); [Dillard, 2000](#); [Harding 1992](#)). In either form, quantitative or qualitative, research is a political project when considering power relations and the impact of research in shaping social worlds. As [Denzin and Giardina \(2019\)](#) argue, "the researcher is historically and locally situated within the very processes being studied" (p. 6), meaning that one's social identities, worldviews, and perspectives will always permeate their approach to research. Challenging the positivist premise of

objectivity in research, critical and feminist theories contest the notion that there is a universal truth or neutral social scientist. Harding (1992) states strong objectivity can be achieved by challenging power dynamics and notions of value-free science. Specifically, she contends the use of standpoint theories can facilitate getting closer to the truth through the inclusion and centering of minoritized perspectives. However, some feminist and postmodernist critics suggest the search for the truth and situated knowledge in standpoint theories even with strong objectivity or reflexivity still subscribe to traditional empiricist approaches and undermine the fluidity in social positions (Naples and Gurr, 2014; Pillow, 2003; Sabzalian, 2018).

Though ideological and theoretical approaches to understanding knowing vary (e.g., differences between standpoint and post-modern feminist approaches), situated perspectives and knowledge involve reckoning with individuals' multiple lived realities that are derived from varied social positions and contexts. As such, when engaging in meaning-making and knowledge production, it is imperative to consider the role of the researcher, their identities, and their world views. Positionalities are "the ways that researchers' cultures work as lenses through which they experience the world, and how they envision and conduct research" (Rogeman et al., 2016, p.44). Among some qualitative scholars, one's positionality can strengthen the research process, particularly when there is a shared identity between the researchers and the participants. This presumption is informed by the dominance of white thought in academic disciplines, the suppression of knowledge produced by marginalized scholars, and epistemic oppression (Collins, 2000; Dotson, 2014). For example, Collins (1986) contends that an outsider *outsider within* can benefit social science research because it "might generate a distinctive standpoint vis-a-vis existing sociological paradigms" (p. S16). Similarly, Delgado Bernal (1998) illustrates cultural intuition is "nurtured through our personal experiences (which are influenced by ancestral wisdom, community memory, and intuition), the literature on and about Chicanas, our professional experiences, and the analytic process we engage in when we are in a central position in our research and our analysis" (p. 567–568).

However, others contest the binaries of outsider versus insider status with origins in anthropology. Applying Linda Tillman' (2002) framework for culturally sensitive research, Rogeman and colleagues (2016) argue "cultures [are] always present throughout research processes and not an additive feature distinct from research processes" (p. 45). Rather than subscribing to fixed notions of outsiders and insiders, one can employ considerations on how the cultural knowledge of the researcher and participant interact. Culturally sensitive research prioritizes centering participants' cultural, co-constructed knowledge through analysis that is reciprocal, ethical, and responsive to power dimensions. While some scholars challenge the dichotomy of outsiders versus insiders in research, some critical social theorists account for the complexities of conducting within-group research in response to overly essentializing and romanticizing in-group status. For example, Collins' (1986, 2000; 2019a) understanding of *outsiders within* emphasizes the importance of antiessentialism by accounting for how social identities are situated in a social context and vary across matrices of domination.

While positionality involves reflection on one's identity and social position shapes their understanding of the social world and impacts the research, reflexivity is practiced (Hesse-Biber, 2014). Sharlene Hesse-Biber (2014) defines reflexivity as "a process by which researchers recognize, examine, and understand how their social background, location, and assumptions can influence the research" (p. 3). Other feminist researchers describe reflexivity "as critical reflection on the ways that researchers, research participants, their communities, and academic audiences create, use, sustain, and reconfigure power within complex, dynamic relationships" (Knight et al., 2004, p. 391). This involves moving beyond simply acknowledging one's positionality but integrating throughout the research process active interrogation on how it influences the construction and representation of knowledge (Knight et al., 2004; Pillow, 2003). "Reflexivity under feminism is not only about investigating the power embedded in one's research but is also about doing research differently." (Pillow, 2003, p. 178). Examining the use and tension of reflexivity as a methodological tool for representation and legitimacy, Pillow (2003) problematizes four ways in which reflexivity is commonly practiced: reflexivity as recognition of self, reflexivity as recognition of other, reflexivity as truth, and reflexivity as transcendence. Using postmodernism, Pillow (2003) posits a need for "uncomfortable reflexivity" as "a reflexivity that seeks to know while at the same time situates this knowing as tenuous" and "rendering the knowing of their selves or their subjects as uncomfortable and uncontainable (p. 188).

The power of positionality in praxis

In sum, researcher positionality and reflexivity are viewed as instrumental in inquiry. The history of exclusion and exploitation in research and science has necessitated reflexivity as a mechanism, though not solely sufficient, to interrogate Western research traditions and dominant knowledge systems. Reflection of researcher positionality and the practice reflexivity are not limited to qualitative inquiry nor addressing status differences and cultural incongruence between researchers and participants. The politics of research compels the need to undertake positionality and reflexivity as integral components of research processes, whether it is quantitative or qualitative inquiry, "white-on-white research" (Phillippo and Nolan, 2022), or research among communities with shared identities. Further, effective engagement of positionality and reflexivity in both the research and writing processes can help challenge white, cisheteronormative logics of identity: as Robinson (2022) reminds, it is possible "to improve reductionist writing about race, gender, and sexuality is in how we do positionality and reflexivity [...] We can turn to embodiment to write positionality in a more nuanced manner, away from static, essentialist notions of identity" (p. 10).

As shown, the methodological process in how positionality and reflexivity are practiced in qualitative research varies. However, essential to transformative research is deep consideration and action that challenges the false premise of the neutral and objective researcher and attention to how research can advance social change (Milner, 2007). As researchers, our positionalities are always with us. Our identities and backgrounds do not leave our psyches as we engage with participants and analyze data. As Rogeman and colleagues (2016) argue, "we take up grappling with positionality not as fixed and located in a physical space where research

occurs, but rather, as it travels with us, within and across multiple social and geographic locations and communities" (p. 47). In the following sections, two authors of this chapter, McLewis and Gutzwa, demonstrate how they have grappled with these realities when conducting research with minoritized communities in education contexts by describing how their positionalities traveled with them throughout the research process.

McLewis' positionality applied: othersisters in feminist research

Employing Critical Race Theory and Black Feminist Thought, my research examined how gendered racism contributes to Black women's pathways to college and their perceptions of their college decisions. I investigated how interlocking forms of oppression operate at both the macro (structural) and micro (interpersonal) level shaped how Black women made decisions about which college to attend and their perceptions of their "choices." My *outsider within* status and identity as a Black woman conducting research with and for Black women granted entry to engage with participants as they storied their educational trajectories. As an outsider, the lack of rapport with prospective participants caused concern about how open students would be to volunteering to participate in my study. After all, rapport is often deemed keen to successfully recruit and engage research participants. Moreover, I was a graduate student and did not attend their campus for my undergraduate education. Surprisingly, however, I found ease in interviewing other Black women. One by one, I would invite women to share about their trajectories to college, beginning with the question: "Tell me about yourself. What's your age, major, what city are you from, and your future aspirations?" Within minutes, students were sharing with me, a perfect stranger, intimate details about their lived experiences that entailed accounts of family drama, secrets, the trauma of sexual violence, challenges and triumphs of navigating educational spaces, and their hopes and dreams. Findings illuminate the extent to which they trusted me and the lack of campus-based spaces and support available specific to Black women's unique needs.

Black feminists describe how a Black feminist standpoint provides a way of knowing and examining research data that is obscured in more traditional research approaches. Our shared identities and similar trajectories made the strange familiar. Their telling of issues related to racial microaggressions from white faculty, predatory male peers disguised as mentors, and colorism and dating retold experiences my Sista-friends and I encountered as undergraduates. In interviewing Black undergraduate women about their college-going experiences, I found that my commitment to social justice, my sense of moral and ethical obligations, and my positionality as the eldest daughter blurred the boundaries of the objective researcher. Dillard (2000) emphasizes that "all views expressed and actions taken related to educational inquiry arise from a personally and culturally defined set of beliefs that render the researcher *responsible* to the members and the well-being of the community from which their very definition arises" (p. 672). As they shared their college experiences, there were instances positions as a researcher shifted into an "othersister" role to assist Black undergraduate women in navigating the university.

Within Black Feminist Thought, othermothers (James, 1993) are "women who assist bloodmothers by sharing mothering responsibilities" (Collins, 2000, p. 178). Collins (2000) describes how historically within the Black community, the realities of intersecting systems of oppression required othermothers, such as extended family members, neighbors, and networks, to play a significant role in providing familial and communal support. Pertinent to this discussion is how community, support, fictive kinship, and social responsibility shape the relationships Black women have with members of broader Black communities. The sentiment of othermothers is thus helpful in conceptualizing the role of Black women and other women of color scholars working with research communities, especially those that reflect their own social identities. I offer "othersisters" to designate the relationship between women of color and their respective research communities.

The role of othersisters in research settings entails the social responsibility associated with conducting research with communities one cares about. My decision to intrude on the research process was guided by the sense of responsibility to ensure that these women were equipped to be academically and socially successful at the university. For example, some of the women I interviewed described challenges in meeting other Black students given the university was a predominately white institution and lacked a Black cultural student center. With my familiarity with cultural affinity and underground social network groups, I shared information about resources on campus. Other actions included sharing information about Title IX offices, providing advice on courses and professors to seek out, assisting in completing financial aid documents, and even scholarship award information to recipients who were unaware that they were fully funded and were working part-time to support their studies—a revelation and indicator of the limited college knowledge and institutional support Black women receive before and after entering a selective university that is based on white middle-class assumptions regarding their needs.

Gutzwa's positionality applied: emic and etic flux in the field

In the early stages of my doctoral career, I embarked on a critical, qualitative study which explored trans collegians' experiences navigating collegiate classroom environments (Gutzwa, 2021b, 2022). At the time, I identified as a cisgender, white, queer settler, placing me firmly outside of the communities the study sought to engage. As such, the power and privilege which my social identities afforded me were constant point of reflection for me in the field. I thought long and hard—to the point of almost stopping—about why I was inspired to do this work, what place I had in working with communities I myself was not a part of, and how I could be furthering damage against an already heavily systemically minoritized community. One way I worked to disrupt the power balance of the research setting was through the use of creative methods, including the writing of poems and the drawing of identity maps, that aimed to decenter traditional white, cisgender modes of knowledge production (Bhattacharya and Payne, 2016; Gutzwa, 2022). Through collecting what Esteban-Guitart (2016) describes as "testimonies of identity" that can illuminate the ways of

knowing students develop throughout their lives and bring with them to educational spaces, this asset-based approach prioritized self-authored narratives of trans student experiences in research design.

Before beginning data collection for the study, it was suggested by a peer that I offer to participate in the creation of “I am from ...” poems and drawings alongside my participants as a way to build a relationship and present my own ways of knowing to them. I still remember the first interview I conducted for the project. When describing the poem elicitation activity to my participant, a nonbinary Student of Color, I offered to complete the exercise alongside them. Immediately, they let out a sigh of relief, saying that my doing so would make them feel more comfortable. Through that poem and the questions my participant asked me that followed, I explained my history with mental health in college, my neurodivergence, my queerness—things that I am open about conversationally, but rarely in such a raw, visceral way. While I believe it impacted my participant’s willingness to share their experiences with me, this was the first moment where I felt conducting qualitative research could also become an act of healing for me, the researcher.

Over the course of the interviews and conversations with my participants in this study, I began to slowly write more through my poems and draw more through my circles than I had ever verbalized before. In essence, I came out to myself as nonbinary through my writing, through these poems, while collecting data. My positionality evolved and shifted every day in the field. Hearing students discuss their experiences with gender and simultaneously exploring sides of my memories and heart that had been sealed away through the trauma of my lived experiences, I came to understand that I no longer identified as a cis man. Through my work, I found myself in the community I was engaging with: My methods were as liberatory for me as they were for my participants.

In her essay and call to action “The transformation of silence into language and action,” Black feminist Audre Lorde (1984b) argued that all feminists ought to be united by their strifes in “reclaiming ... that language that has been made to work against us” (p. 43). Employing decolonial methods in my research methods through a critical, queer, feminist lens enabled me to actualize Lorde’s words—not just to reclaim words that subjugate my communities and the communities I work with, but also to reclaim the language that has been weaponized against me throughout the course of my life. Through taking a critical approach in understanding gender in my research, I not only build rapport with participants but also intimately interrogated my positionality in the field. This reflexive process further embodies Robinson’s (2022) non-binary knowledge production: in writing this thick description of my own positionality, “I follow the queer routes that my mind and life take me”, highlighting the ways the evolution of my identities and my relationality to those who I engaged in research with both shapes my meaning making of trans experiences and serves as a rejection of hegemonic white, cisheteronormative tensions in qualitative research (p. 3).

Conclusion

In this chapter, we explored how critical social and feminist theories can be employed to advance research and the complexity of gender in the field of education. We complicate the examination of gender in research that fails to interrogate how gender is socially constructed and its intersection with other forms of domination and power. As stated by Stewart (2022), “Containing (limiting) diversity, in ways that reify normative understandings of identity and diversity, undermines the ability of researchers to uncover findings that would lead to implications capacious enough to effect transformation and disrupt structures of oppression.” (p. 62). Advancing a transformative research agenda insists on disrupting oppressive ideologies and assumptions embedded in research practices that are implemented by researchers. While we present critical social and feminist theories as frameworks that can be utilized when forging transformative research, we caution the mere application of these theories (or methods) without intentional integration of disruptive practices throughout research processes.

Addressing the liberatory and empowering aims of a transformative research agenda opens opportunities for gender-based research in education to become a mutually dialogic process, potentially becoming as transformative for researchers as it is for participants in building resistance to dominant ideologies and frames. Fundamental to this work, however, is that researchers interrogate their own investment in the inequities they seek to study and engage in greater self-awareness regarding their own identities, epistemologies, and relationship with participants. This process requires much more than simply laying bare one’s biases in a positionality statement to increase the trustworthiness of a study. Intentionally interrogating one’s positionality necessitates also considering how the researcher sees their role as an agent of change, seeks to disrupt reinforcing systems of oppression to extend educational opportunities, improves outcomes for minoritized groups and communities, and dares to reimagine new possibilities of education environments and research. More examples and descriptions of methods for increasing reflexivity and ways to debrief that liberate the researcher from dominant assumptions are needed in the literature.

In contrast, an increasing number of creative methods have arisen to amplify the voices of gender-identity groups in the literature, conveying their perspectives and agency. These methods and methodologies are oftentimes not taught in traditional methods classes, but instead are more often derived from the cultural communities that researchers and participants belong to which are then subsequently shared among and adopted by communities of researchers. These communities, comprised of both knowledge constructors and seekers, provide the energy and insight needed to dismantle interlocking forms of oppression, ultimately harnessing the liberatory and transformative potential of educational research and praxis.

Glossary

Colorblindness or colorblind ideology Refers to a worldview that disregards race or racial characteristics. In practice it is a method of disregarding race as a criterion used for selection of participation or receipt of services

Critical race theory A multi-disciplinary approach rooted in critical legal theory that combines social activism with a critique of the fundamental role played by racism, white supremacy, and white privilege in shaping contemporary societies

Interest convergence principle An analysis, first proposed by critical legal scholar Derrick Bell, noting that advances in race equality have historically come about only when white elites see the changes as in their own interest; especially as a means of limiting civil unrest and protecting against fundamental societal change

Intersectionality An approach that is especially sensitive to the ways in which multiple axes of oppression interact, e.g., analyzing how racism operates within and across factors such as social class and gender

Jurisprudence Refers to the theory or philosophy of law. In this article it primarily refers to the dominant legal thought which excludes and marginalizes racial minorities in the United States

Meritocracy Refers to a system of rewards based on the ability and talent of individuals, leaving unaccounted for the structural advantages and disadvantages conferred to different groups in society

Positivism As it concerns social reality and knowledge is the notion that both exist objectively and independently of social actors

Race Refers to a socially constructed classification used to categorize people into groups based on phenotype and characteristics assumed to be inherently shared

White privilege Any phenomena, whether individual, structural, political, economic, or social, that serve to benefit white people while oppressing people of color. The tangible benefits of access to resources and social rewards which whites receive, coupled with the power to shape the norms and values of society, unconsciously or consciously, by virtue of their skin color

White supremacy Commonly refers to individuals and groups who engage in the crudest, most obvious acts of race hatred (such as the Ku Klux Klan and other extremist nationalists and neo-Nazis). In critical race theory the term refers to a regime of assumptions and practices that constantly privilege the interests of white people but are so deeply rooted that they appear normal to most persons in the culture

Introduction

There has probably never been a more apropos time for education scholars to define what critical race theory (CRT) is (and is not), to revisit its historical foundations and original intent, and to trace its application in educational research. Specifically, this chapter updates and synthesizes two extant chapter reviews of CRT in this encyclopedia series (see “Tagline”) and pushes further the exploration of CRT as a theoretical framework for educational research that utilizes qualitative methods. Although an exhaustive list of the theoretical elements and arguments of CRT scholars is beyond the scope of this article (see [Ledesma and Calderon, 2015](#)), the key principles presented provide a basic understanding of its theoretical underpinnings. However, since CRT became such a political lightning rod under the United States presidential administration of Donald J. Trump (2017–2021), and is currently being contested vociferously in state gubernatorial, legislative, and educational bodies across the country ([Sawchuk, 2021](#), May 18; [Wallace-Wells, 2021](#), June 18), we begin with a brief overview of the present context. Second, we define CRT and review its historical and legal foundations. Third, we offer a description of CRT’s resonance in fields beyond law, namely education, and present examples of qualitative research where it is employed to elucidate issues in this field. Finally, we conclude with implications for the future of educational research framed by CRT and qualitative methods.

Critical race theory under attack

The term “critical race theory” has been bulldozed out of the confines of academia and into the mainstream of American political discourse since the Trump era ([Sawchuk, 2021](#), May 18; [Wallace-Wells, 2021](#), June 18). Under the Trump administration, with calculated counsel from Christopher Rufo, a Seattle-based conservative think tank consultant once profiled on Fox News, this discourse took the decidedly polemical turn of denouncing CRT tenets and any acknowledgment of white privilege in federal racial sensitivity training programs wholesale ([Wallace-Wells, 2021](#), June 18). Namely, *Executive Order on Advancing Racial Equity and Support for Underserved Communities through the Federal Government* (<https://www.archives.gov/presidential-libraries/archived-websites>) issued by the Director of the Office of Budget and Management, ordered all federal agencies to cease all racial sensitivity trainings on white privilege and critical race theory citing them as “divisive anti-American propaganda.” The memo took specific aim at any CRT training espousing that “virtually all White people contribute to racism” or “benefit from racism.”

Notably, since January 2021, thirty-five states have introduced bills or taken steps to restrict teachers from teaching CRT ([Schwartz, 2022](#), February 4; [Associated Press, 2022](#), January 19). Conservative gubernatorial candidates have been hedging their bets on winning campaigns partly on *anti-CRT* platforms with the most recent election upset leveled by Virginia’s Republican Governor Glenn Youngkin, who has vowed to abolish CRT in public education and government ([Beauchamp, 2021](#), November 4). In response, many K-12 and higher educators and administrators across the country are confused, worried, and tentative about whether and how they should be teaching about race and racism in United States history and current events. There are mounting concerns that *anti-CRT* backlash is having a “chilling effect” not only on using CRT frameworks but also on the teaching and training of diversity, equity, and inclusion topics writ large, especially those focused on race, gender expression, and sexuality ([Harvard Law Review, 2020](#), February 10; [Collman, 2021](#), September 2). Yet many educators are joining ranks with legal, civic, and academic organizations to fight back.

This polarizing context underscores the importance of clarifying the definition, origins, and significance of CRT in educational research, particularly to counter myths and misunderstandings of CRT. Three myths or misunderstandings seem particularly common. The first is that CRT views race as the source of all major inequalities. This myth will be addressed in a subsequent section on intersectionality. The second is that CRT views white people as uniformly racist and privileged. While CRT does implicate racism as an endemic system that benefits whites uniformly, this does not mean that it does not recognize how poverty, gender, and other forms of oppression differentiate the experiences of whites. It also does not support the view that whites cannot be genuinely invested in *anti-racist* causes. Finally, there is the myth that CRT promotes a sense of hopelessness and pessimism. Although scholars and individuals who view racism as endemic to society within the United States tend to offer many critiques, they also hold out hope for a more democratic, just, and inclusive society if indeed the root causes of inequality and injustice are called out and sufficiently addressed. Delgado and Stefancic responded to this myth by inquiring, “Is medicine pessimistic because it focuses on diseases and traumas?” (2001, p. 13).

Critical race theory’s definition and legal foundations

CRT recognizes racism as systemic and endemic to American society across all spheres—education, housing, employment, health-care, etc. ([NAACP Legal Defense Fund, n. d.](#)). It is an academic, multi-disciplinary approach rooted in critical legal theory that combines social activism with a critique of the fundamental role played by racism, white supremacy, and white privilege in shaping contemporary societies. More broadly, CRT is an evolving movement formalized in the legal field during the 1970s in order to grapple with the nexus between race, racism, and American jurisprudence, in a more constructive manner ([Bell, 1987, 1992](#); [Crenshaw, 1988](#)). The term critical race theory was coined in the 1980s by legal scholars, mostly people of color, who were dissatisfied with existing approaches to the field.

CRT's emergence represents a response to the retrenchment of civil rights reform. This accounts for critical race scholars' critique of civil rights doctrine (which espouses equal treatment) and dissatisfaction with traditional legal reform. Both legal ideals were viewed as inadequate for the emancipation of people of color and susceptible to discourses supporting neoconservative agendas to reinstate racial subordination. Accordingly, CRT was formulated by scholars whose primary concern was advancing a theory and method for examining race and overcoming racial inequality through critical analysis of legal doctrines.

Though critical race theorists vary in the scope of their study, at least five central tenets guide its use in education (i.e., theory, research, pedagogy, curriculum, and policy): "Centrality of race and racism and their intersectionality with other forms of subordination, the challenge to dominant ideology, the commitment to social justice, the centrality of experiential knowledge, and the transdisciplinary perspective" (Solórzano et al., 2000, p. 63). The use of CRT in education is appropriate for several reasons; however, the main justification extends its emergence out of critical legal studies (CLS) both in its points of alignment and departure. Thus, before addressing CRT in education some discussion of its emergence in critical legal theory merits attention.

Critical legal theory

CRT is considered to have its origins in a departure from the theorizing of CLS. While the critical race movement's inception is marked by critiques of legal scholars, most of whom were scholars of color (such as Derrick Bell, Richard Delgado, Allan Freeman, and later scholars, such as Kimberle' Williams Crenshaw, Angela Harris, and Mari Matsuda) within the legal studies movement, the formulation of CRT is inherently informed by a myriad of previous movements—including (among others) feminism and the spirit of the civil rights movement encompassing a long legacy of resistance to racial subordination (Delgado and Stefancic, 2001)—and literature across multiple disciplines (Yosso, 2005). However, legal scholars were instrumental in informing the constructs that ultimately have come to define the critical race movement and theory.

The emergence of CRT is more than simply an extension of CLS: it serves as a critique. Although critical race theories and critical legal theories are separate and in contention with one another, they share some notions about how law operates in society. Broadly, the critical legal movement emerged to counter presumptions that the law operates in a neutral and objective manner (Hunt, 1986). Specifically, it advocates notions of realism, a movement "developed out of the dissatisfaction with tenets of classical legal thought that cast judicial decision as the product of reasoning from a finite set of determined rules" (White, 1972 as cited in Tate, 1997, p. 207). Thus, CLS provides an analytical lens to critically examine legal ideology and discourse as a mechanism to socially reproduce and legitimate inequality within society (Hunt, 1986; Tate, 1997). In alignment with this tradition, Tate's (1997) review of CRT origins notes that critical legal theories provide two important critiques that would ultimately inform CRT: these include a critique of formalism and objectivism. The first is characterized by "impersonal purposes, policies, and principles that serve as the foundation for legal reasoning" while the latter assumes the legal system provides an intelligible moral order (Tate, 1997, p. 208). Therefore, critical legal theorists offer a critique of law which acknowledges legal ideology and legal structures of authority as producing and maintaining social inequality, as opposed to functionalist views viewing social inequality as natural. This critique has served critical race theorists in their interrogation of inconsistencies within legal doctrines, specifically explanations of the contradictions and therefore negative consequential effects of civil rights law on progressive racial reform (i.e., Bell, 1976, 1980; Freeman, 1995). For these reasons, Matsuda (1995) described, "[t]he willingness to at least consider the utopian prospect and the enthusiastic criticism of existing conditions of racism and poverty attract nonwhite readers to CLS" (p. 64). Given the legacy of racial inequality within the United States, largely maintained through the construction of laws, critical legal theories share an important perspective with the critical race theorist, which is necessary for understanding the nexus between law and oppression.

Despite its utility, critical race theorists point to limitations of critical legal theories, which render them inadequate for understanding experiences of populations of color. Dalton (1995) wrote, as scholars of color within the CLS movement they "are always invited in for tea, but rarely invited to stay for supper, lest we use the wrong intellectual fork" (p. 80), specifically speaking to the limits and determinism that CLS's hegemonic view of rights doctrine poses for people of color. The collective response to sentiments of disempowerment and intellectual differentiation resulted in CRT; that is, a movement which foregrounds the lived experiences of people of color in order to both acknowledge their marginalization in American jurisprudence but also enable a vision of law that holds the potential for social justice in terms of equal rights, status, and material outcomes. While there are multiple theoretical discontents, including inability to offer structures for social change, a central critique that critical race theorists have of critical legal theories is the assumption that racism is the same as other forms of oppression (Delgado and Stefancic, 1993). Utilizing legal theorists' critiques of legal doctrine as a foundation for their own work, critical race theorists brought the racial dimension to the forefront of the analysis: race, they assert, is crucial for understanding and ultimately overcoming inequality given racial saliency in the United States.

Grounded in traditions of the critical legal theorist, Bell's early writings (including Bell, 1976, 1980) have been identified as "the intellectual starting point of Critical Race Theory" (Crenshaw et al., 1995, p. 3). Crenshaw and colleagues believe that while Bell's critiques of civil rights discourse represent critical legal critiques of the time, his use of a race-conscious perspective that (1) focused specifically on the effect on Blacks and (2) presented legal decisions as reflective of white racial interests, was a departure in perspective, marking the development of CRT. Specifically, Bell's (1980) concept of interest convergence—the argument that basic rights are provided only when they meet the shared interests of and do not harm the benefits of whites—was significant in propelling forward the critical race movement, especially as scholars of color worked to construct a theory in which race centered as an important, necessary basis of analysis.

Centrality of race

The centrality of race is one of the distinguishing factors of CRT (Delgado and Stefancic, 1993; Solórzano et al., 2000). Crenshaw (1988) pointed to the importance of race as a basis of analysis, given the legacy of racial oppression in the United States. She argued to ignore claims that race is illogical, especially when race has become so deeply embedded in how institutions operate to produce social inequality. For that reason, critical race theorists argue that race is significant and excluding race from the analysis merely veils rather than halts its influence in research, policy, and practice. By bringing race to the forefront of the analysis, critical race theorists explicate the presence use of race. Therefore, revealing race consciousness will illuminate what has traditionally been ignored or hidden in past analysis.

By evoking principles of equality while ignoring the cumulated effects of race reification in material conditions, the concept of colorblindness is deployed to eliminate progressive gains of racial minorities. A well-known and debated contemporary example of this is present in debates over the issue of affirmative action in United States higher education. Opponents of affirmative action argue that race-based sanctions are unjust because they betray a fair approach by privileging people of color over whites. To ground their arguments, opponents call forth the contradictions that affirmative action poses to treating all people as equal. Embedded within this discourse is the notion of a meritocracy, which is a system of rewards believed to be based on demonstrated talent and ability of an individual. Both simultaneously work to undermine social reform addressing race inequities. The use of colorblind ideology to dismantle affirmative action policies exemplifies critical race legal scholars' critiques of civil rights doctrine, and more broadly liberalism, which is ambiguous and potentially serves to disarm progressive efforts toward social justice. In principle alone, arguments grounded in colorblind discourses may appear to adhere to moral reasoning; however, this rationale leaves accounted for the historical and sociocultural contexts that justify the need for affirmative action practices.

Crenshaw (1988) addressed the notion of equality by framing it in terms of equal process and equal outcomes. Using the terms restrictive and expansive equality Crenshaw argued that equal processes are not always indicative of equal outcomes. In accord with the earlier work of Freeman (1995), who used the competing concepts of perpetrator and victim perspectives of racism to explicate race (and consequently non-neutral nature) in law, Crenshaw pointed to the absence of historical continuity in rationalizing colorblind approaches to equality. The notion of equality as used to support the elimination of race-based initiatives fails to acknowledge the presence of different opportunities, erroneously positioning whites as the true victims. As such, race as used in the case of explaining affirmative action, and more generally law in the United States is important because it explicates the presence of race and the role of racism in ideology, structures, and practices.

Similarly, Tate (1997) raised the issue of race as critical for understanding law, education, and society. Arguments for including race are based on the premise that a colorblind approach requires a consciousness of race to be able to reject its consideration (Aleinikoff, 1991 as cited in Tate, 1997, p. 203). In this regard, ignoring race merely disguises rather than eliminates its significance to debates. In citing Justice Harry Blackmun's dissenting opinion in the *Bakke* decision, this argument is exemplary of critical race thought: "In order to get beyond racism [to color blindness], we must first consider race. There is no other way" (Regents of the University of California vs. *Bakke*, 1978, p. 407 as cited in Tate, 1997, p. 203). More importantly, recognizing that race exists unveils the construction of whiteness as normative. Critical race theorists put forth race as a strong analytical tool for understanding and overcoming racism. Therefore, CRT's advancement in the legal field serves to further deconstruct the law, which was formed (and evolved) to maintain racial privileges of one group and consequently legalize the oppression of another; all factors which betray the objectiveness it presupposes.

Although race is a central feature of CRT critical race scholars recognize the role of multiple forms of subordination including class, gender, and sexuality operating in society and law. Therefore, embedded within the critical race framework is a rejection and critique of essentialism, that is, the presumption of a monolithic experience for a particular group with a number of shared cultural characteristics (Delgado and Stefancic, 2001). *Anti-essentialism* is the notion there is no singular experience for people of color, Black people, or any other socially-constructed group. To further advance the *anti-essentialism* thesis, critical race feminist scholars proposed intersectionality to more meaningfully account for the unique ways in which multiple forms of oppression interact to shape the lived experiences of those with multiple identity (Collins, 1996). Intersectionality does not merely suggest that multiple identities are additive, but that their intersectional nature create a unique social location of marginality as well as the potential for ground breaking social and political empowerment. For example, Crenshaw (1995) described how both feminists and antiracist discourses have failed to adequately consider women of color's intersectional identities. Notably, other Black feminist and womanist scholars and authors have addressed this failure in seminal texts such as *Black Feminist Thought*, *Ain't I a Woman*, *Sister Outsider*, and *In Search of Our Mother's Gardens* (Collins, 2000; Hooks, 1981; Lorde, 1984; and Walker, 1983). Therefore, the centrality of race is not to minimize the role of these other forms of oppression, but instead to recognize its social construction largely through legal processes (among other means), such as the formation of the Constitution, which continue to influence society. Critical race scholarship works under the notion that racial subordination is intricately linked to other forms of oppression; thus, dismantling racial inequity is a step toward achieving social injustice.

The centrality of experiential knowledge

Within the CRT movement is the commitment to voice scholarship, which centers experiential knowledge as important. Critical race scholars emphasize the importance of localized narratives, which helps to contextualize and provide understanding. This incorporates a methodological and theoretical approach of perspective taking that requires "looking to the bottom,"—the oppressed of

society—to effectively elucidate and appreciate the complexities of their struggle, both material and ideological (Matsuda, 1995). Further, Delgado (1989) argued that a method of including the experiential knowledge of people of color counters the way traditional legal scholarship conducts analysis. Given that many legal scholars embrace universalism over particularity, the perspective tends to minimize anything that is historical, contextual, or specific with the unscholarly descriptors of literacy or personal (Tate, 1997, p. 220). Critical race theorists argue for the inclusion of these factors in helping to explain the realities of people of color, which are often marginalized in the presentation of law and society generally.

Bringing attention to whose voice is included and reflected in the dominant narrative points to the larger issue of what is considered legitimate knowledge in scholarship. Bringing radicalized lenses to the discussion not only gives voice to marginalized communities, but also offers a critique of the dominant ideology of what is understood as valid knowledge. The inclusion of narratives of people of color in understanding and reforming law counters the dominant discourse and challenges the racial construction of whiteness as the norm by which standards and merit are judged. Universal truths and methods of reasoning as they have been constructed in law are inherently biased toward privileging the dominant group. This is exemplified in Freeman's (1995) analysis of court decisions on civil rights cases of the past century, asserting that the court often adopted a perpetrator perspective of racial discrimination—viewing “racial discrimination not as a social phenomenon but merely as the misguided conduct of particular actors” (p. 30)—a process that consequently negates the victim perspective of discrimination which names the inequities in outcomes and conditions. Accordingly, CRT scholars emphasize subjectivity in experiences, which account for the differences in reality (Delgado, 1989). Thus, where they previously have been silenced, centering on the lived experiences of people of color, voice is a crucial concern of analysis and methodology, both for legal policy and for educational research.

Researcher positionality

Related to this concept of voice, as it involves inclusion of people of color, is the role of the scholar and researcher. This aspect has been addressed by critical race scholars, who find themselves as outside scholars, marginal within their fields of study (Delgado, 1984, 1992). Specifically, scholars like Delgado (1984) have called attention to how the ethos of academia perpetuates dominant narratives and inadvertently works to de-legitimize and silence scholars of color, particularly in discussions concerning minority rights (i.e., civil rights). Additionally, this critique has led to employing methodology which includes reflexive processes of self-interrogation (particularly for white scholars, discussed in more detail below), interrogating how scholars' worldviews inform, understand, and contextualize the textual product. These aspects of theory and methodology are at the heart of CRT.

Notably, researchers must be aware of their own positionality—that is, awareness and understanding of how their racial and/or ethnic identities may position them in a larger system of privilege, power, and/or oppression that affects their own personal experiences, the perceptions of their research participants' experiences, and the possibility of creating deficit discourse within their work (Coghlan and Brydon-Miller, 2014; Milner, 2007). Milner (2007) noted that it was not so much that researchers must represent the identities both racially and culturally of their study participants, but more so that they must “be actively engaged, thoughtful, and forthright regarding tensions that can surface when conducting research where issues of race and culture are concerned” (p. 388). This is important because the experiences of people of color are shaped by the various attributes of their identities and most significantly by their race, ethnicity, and cultural heritage. Therefore, it is important for researchers to be conscientious of the potential for implicit bias, that is, the unconscious act of prejudice and/or stereotyping, to appear within their work (Brownstein, 2019). Hence, researchers must be held accountable for the discourse they use to present their work and how it represents their participants and their participants' communities.

For this reason, much discussion is needed concerning the presence and approach of white scholars utilizing CRT as advocates against racial injustice. Bergerson (2003) learned through discussions with her colleagues of color that “for whites to move into the area of CRT would be a form of colonization in which we [white scholars] would take over CRT to promote our own interests or recenter our positions while attempting to ‘represent’ people of color” (p. 52). Because whiteness allows one to remove an awareness of race, it also creates a power dynamic where whites are able to define the attributes of other races. Therefore, whiteness becomes the norm and can give a false sense of colorblindness—the idea that race no longer matters (Bonilla-Silva, 2013). As noted previously, the notion of colorblindness provides an avenue for racism to persist within a white-normed environment that gives an inequitable preference to people of color who appear whiter (Bergerson, 2003). Unfortunately, this also attributes further to issues of colorism—giving preferential treatment to those of lighter skin tone by people of color within communities of color (Glenn, 2008; Wiggins, 2021).

Therefore, white scholars must rethink their positioning when conducting research within communities of color and their utilization of CRT. In particular, white scholars must acknowledge their privileged perspectives and the benefits that they receive due to their whiteness (Bergerson, 2003). In addition, white scholars must center their concepts of race by seeing whiteness as a non-neutral race; hence, dispelling the concept of colorblindness (Bonilla-Silva, 2013). People of color developed CRT to provide counter-narratives and give understanding of their lived experiences (DeCuir-Gunby et al., 2019; Delgado and Stefancic, 2017). Thus, white scholars must utilize the tenets of CRT as a way to inform their concepts of race and as advocates by insisting “that CRT is a legitimate method and lens for studying racism” and therefore, normalizing its application by citing those who have used it (Bergerson, 2003, p. 60). Because CRT can be utilized to create an understanding of the lived experiences of people of color and how race-neutral policies and practices continue to perpetuate racism within their lives and communities (Parker, 2015; Parker and Lynn, 2002), scholars who utilize CRT must recognize their privilege, position to power, and/or ability to oppress in order to ensure that their work does not further acts of racism but creates change.

Narratives, stories, and counterstories

The critical race movement was founded on the works of scholars such as Derrick Bell and Richard Delgado, who employed and established a narrative tradition, which departed from mainstream legal scholarship and was more commonly found in literature. These include the use of “parables, chronicles, stories, counterstories, poetry, fiction, and revisionist histories” (Ladson-Billings and Tate, 1995). These narrative forms enable scholars to challenge dominant discourses that propagate stereotypes and distorted images of people of color. Appropriately termed counterstories, they exist as a method for conveying the untold experiences of marginalized groups, and also function as a tool for analyzing dominant narratives presumed to be reality. Strauss and Corbin (1990) were early pioneers of this process by coining early forms of this approach as theoretical sensitivity. This sensitivity is achieved by collecting data from sources that have been collected by the true lived experience surrounding the phenomenon being explored, (Solórzano and Yosso, 2002). Data sources within counter-storytelling methods include the researcher’s own experiences and data collected from the research process itself. Even though counter-storytelling is the method often utilized by qualitative CRT scholars, other methods have included first person narratives, critical race grounded theory, and problem-posing methodology (Smith-Maddox and Solórzano, 2002).

Among the reasons for utilizing counterstories include (1) community-building; (2) challenging the perceived wisdom of the those at the center of society; (3) self-preservation for marginalized groups; (4) constructing a richer description of issues and stories that reality alone may be unable to provide; and (5) providing a context for understanding and challenging established belief systems (Delgado, 1989; Lawson, 1995 as cited in Solórzano and Yosso, 2002). While stories are a critical part of the critical race tradition, their use is highly contentious and is not universally accepted as appropriate for the academy. Still, CRT scholars argue that this method is valid, and critiques originate from a positivist paradigm which privileges the normative nature of whiteness as the status quo. Further, they argue that counterstories are necessary particularly since reality is socially constructed and therefore stories from people of color’s lived experiences can illuminate their circumstances, since the experiences of whites are privileged in the dominant or majoritarian narrative (Delgado, 1989).

Branches of critical race theory and its applications in disciplines beyond law

While CRT is largely used in the legal field, the theory has been adopted by scholars in fields such as sociology (Christian et al., 2019). The approach grew in popularity and transcended its disciplinary boundaries, moving into educational studies in the mid-1990s (Ladson Billings and Tate, 1995). Scholars in these fields continue to utilize and advance CRT’s core tenets—most notably the centrality of race and experiential knowledge. Therefore, it is a reductionist misrepresentation to declare that CRT is confined solely to the legal academic realm. Although CRT originated in the legal field, the theory has made its way into multiple fields. In addition to sociology and education, due to its interdisciplinary focus, CRT literature also overlaps with literature from fields such as women studies, ethnic studies, and history.

Critical race theory has also been advanced to offer new insights and innovative critiques of previous theories as well as issues within these fields. For example, CRT as a theoretical construct has expanded to incorporate, or further illuminate among extant theories, the experiences of women (FemCrit, Black feminist thought, and womanism), Latinas/os (LatCrit), Native Americans (TribalCrit), Asian Americans (AsianCrit), sexualities, genders, and other social identities that fall outside normative identities (QueerCrit). Even white scholars have drawn inspiration from CRT (WhiteCrit) to examine and challenge white privilege and supremacy often under the umbrella of “whiteness” studies. These branches of CRT move beyond the Black/white binary that CRT critiques tended to follow, understandably, as their critiques were originally focused on civil rights legislation (Yosso, 2005). Therefore, CRT has become more nuanced as it is applied to multiple experiences of people of color.

Yet, just as each of these expansions represents the varied issues and priorities within and between communities of color and socially marginalized groups, CRT scholars acknowledge, “the institution of slavery is foundational in American racism” and instructive for the struggle against multiple oppressive “isms” beyond the Black–White paradigm (Matsuda, 2002, p. 397). Notably, the recent emergence of a Black Critical Race Theory or BlackCrit perspective recenters concerns about Black people’s experiences in an *anti*-Black society (Dumas and ross, 2016). BlackCrit asserts that *anti*-Blackness is endemic in global society and is in tension with notions of multiculturalism. Moving beyond what some observers view as a pessimistic tenor of CRT, BlackCrit encourages Blacks to envision—even fantasize—a liberatory future unfettered by the legacy of slavery and oppression.

Critical race theory in educational research

CRT is used in education to frame how institutions maintain racism, sexism, and classism through structures, processes, and discourses. Ladson-Billings and Tate (1995) initially introduced CRT to the field of education, arguing that race has gone virtually untheorized in understanding issues of education. Together, they put forth CRT as a theory for understanding and overcoming school and educational inequity. Since then, a growing number of scholars began employing CRT in education to elucidate how educational practices and widely accepted theories minimize the importance of race and/or perpetuate a system which oppresses, subordinates, and marginalizes African American, Latino/a, Asian American, and Native American students. Solórzano and Yosso (2001) contended that stereotypes and deficit frames used in elementary and secondary educational practices reproduce social inequities. Educational practitioners, who subscribe to these stereotypes, suggest that students of color are intellectually inferior, lack

motivation, and are destined to become engaged in criminal activity. Additionally, educational practitioners have used deficit-framed perspectives to explain the academic underachievement of students of color. These frameworks often put the onus of blame on student and/or his or her culture for poor academic performance. For example, deficit-frame employers may state, "African Americans (or Latinos) do not perform academically because African American (or Latino) culture does not emphasize education." Clearly, the unequal resources, the quality of education, and societal inequities are not considered in these deficit frames. As a result, these educational inequities may be manifested in low expectations for African American, Latino/a, and Native American students, tracking, remediating the curriculum, and limiting access to high-level or advanced placement courses (Solórzano and Yosso, 2001; Darling-Hammond, 2001).

Reframing dominant educational theory through a critical race perspective

CRT is used to reconceptualize dominant educational theory, which has been framed around European American cultural values. A noteworthy example is Yosso (2005), who uses CRT to reframe the Bordieuan theory of cultural capital, which is a narrowly defined theory based on "White, middle class values, and is more limited than wealth—one's accumulated assets and resources" (p. 77). Yosso expanded this view to include cultural capital more representative of communities of color, which include aspirational capital (maintain hopes and dreams), familial capital (cultural knowledge and community history), linguistic capital (skill gained from communicating in more than one language), social capital (networks and community resources), navigational capital (negotiate social institutions), and resistant capital (knowledge and skill gained from opposing inequality). Collectively, Yosso referred to this new cultural capital frame as a community of cultural wealth.

Similarly, Patton et al. (2007) used a critical race frame to problematize racelessness (p. 43) in prevailing college student development theories. An example of a raceless college student development theory is in Chickering and Reisser's (1993) *Education and Identity*, which gives limited treatment to the role of race in identity development. Additionally, Patton et al. pointed out that some scholars have used homogeneously white samples to inform the theories they developed. Subsequently, these theories are applied to college students in general and do not account for the experiences of college students of color. Patton et al. suggested "Color-blind racism and racial indifference must consistently be challenged through exposing the manner in which racial advances often come at the cost of promoting or feeding into White self-interests" (p. 43).

Files' (2021) dissertation, "Mothering Ourselves to Wholeness," worked to uncover the myriad ways Black mothers in life and literature have forged communal wholeness, protected the most vulnerable, and healed harm outside and within communities. In this work, the conceptual framework of Black Mothering Praxis (BMP) constellates the communal practices that counter exploitation, center care, bolster accountability, and foster wholeness in a world that often breaks and fragments Black bodies and beings. Integrating Critical Race Parenting (CRP), Black Feminist Thought (BFT), and Black Mothering (BM) as theoretical frameworks, this research began with identifying the various ways Black mothers have been read as a "problem" in research. It contends that even though BFT has, in some ways, become more mainstream, racist misreadings of Black mothers as deficient and unfit persist. Files (2021) noted how numerous researchers have worked to address Black mothers' misreadings, stereotyping, framing, criminalization, and dehumanization. However, according to Files (2021), few studies move beyond the framing and re-imagining of Black motherhood and Black mothering and build a path for exploring how Black mothers' portrayal in literary texts can be connected to the narratives that real-world Black mothers tell. This research engages those narratives to instruct us in creating more livable and loving communities, based on the Black Mothering Praxis of rural, urban, and suburban Black mothers, and the Black mother characters that show up in Black women's literature. The research gathered the narratives of fourteen socially and politically engaged Black mothers and thematically analyzed those narratives to find particularities and commonalities. The themes emerged and highlighted connection to elders, self-care, and freedom dreams as central to the Black mothers' stories. Moreover, Files (2021) engaged in rigorous Black literary critic to understand the ways Black mothers are represented in fictive narratives. Drawing from Black feminism(s) and critical race theory, the research concludes that Black mothering practices activate freedom, resist oppression, and restore community wholeness. Finally, the work demonstrated how Black mothers' life stories in literature and across regional contexts clear pathways for fostering communal care and accountability.

Exemplified through the works reviewed, CRT can aid scholars in reshaping the discourse around students, families, and communities of color in educational research. Previously, the norms and values of dominant cultural groups were juxtaposed with those of communities of color, resulting in an assimilationist approach to dealing with students of color. This approach suggests that students must discard cultural values not aligned with the dominant frame in order to succeed. As a result, students' (of color) culture is to blame for their academic underperformance and not the system maladaptive to multiple points of view. CRT has given scholars and practitioners the tools to reevaluate theoretical perspectives and educational practices from multiracial and multicultural perspectives.

CRT and qualitative methods in educational research

Educational researchers have effectively utilized CRT to frame empirical research applying qualitative methods. For example, CRT-based research has been used to explain the importance of family and culture in education, the experiences of Black males in higher

education, the role of racial micro-aggressions in the perceived college-campus climate of students of color, and intra-racial concerns among Black collegiate women. In these contexts, CRT goes beyond simply describing a problem or challenges associated with educational outcomes and experiences; it explicates the sources of persisting problems, which is very often grounded in systemic racism and oppression.

Focusing on ethnographic studies of Latino/a families and education, Villenas and Deyhle (1999) used CRT to position schools' and larger society's negative perceptions of cultural differences in family socialization and education within a framework of power relations and the castification of Latinos/as in the United States. They found that Latino families play key roles resisting assaults on Latino/a culture. The history of Latinos as taught from the dominant White ideology, propagates views of Latinos/as illegal immigrants and foreigners. The ethnographic studies demonstrate how Latino/a families can take collective action to transform the schooling of their children. Clearly, CRT can be used to identify counternarratives that "challenge dominant culture's 'stock stories' which legitimize the world views of White, upper-class United States" (p. 441).

CRT perspectives and qualitative methods have been used to examine the experiences of Black males within educational institutions (Ladson-Billings and Tate, 2006; Hiraldo, 2010). In particular, CRT has helped to provide counternarratives to demonstrate Black male student success as well as challenge the dominant culture's deficit-oriented narratives surrounding Black male achievement (Jones, 2021). Harper (2009) used CRT's counternarratives to understand the experiences of high achieving Black male college students and to demonstrate their resilience in spite of the various barriers placed on them by administrators and educators alike. By capturing firsthand narratives of Black males, CRT has contributed to a research paradigm that is no longer focused on the deficit narratives which have been the focus of previous Black male research (Harper, 2009). Centering the voices of Black males acknowledges their resiliency and supports solving the challenges they face within education (Jones, 2021).

A CRT perspective can also elucidate the atmospheric nature of racism in educational institutions as hostile climates for students of color. Solórzano et al. (2000) used CRT to describe the experiences of African American students attending predominantly white research universities. Participants in this study shared their experiences with everyday subtle forms of racism and stereotypes (micro-aggressions). Examples of these micro-aggressions include feeling invisible as one of only a few African Americans in a particular college classroom, faculty having low expectations, challenges in joining study groups with non-African American students and feeling a sense of hyper-surveillance because of perceived criminality. Micro-aggressions created a negative campus racial climate, which led to feelings of frustration, isolation, self-doubt, and exhaustion. Many students in this study coped with the negative campus racial climate by creating counterspaces where they could be surrounded by supportive peers and collectively reject the notions of intellectual inferiority and stereotypes of deviance or criminality.

Finally, CRT coupled with qualitative methods can address intra-racial concerns, of course, understood within the context of racism, white supremacy, and white privilege. According to Wiggins (2021), colorism perpetuates the same variables that drive the principles of racism and has led to disparate treatment, lower self-esteem, and negative perceptions within communities of color, particularly among Black women, for decades. Since Black women are considered second class citizens, behind both men and white women, it is vital to acknowledge that their experiences with racism, compounded by colorism, are most salient. In her qualitative research study entitled *Shades of Black: Black Collegiate Women and the Impact of Colorism in Higher Education*, Wiggins set out to: (1) explore colorism as a phenomenon while also investigating its impact on the higher education attainment of Black collegiate women, (2) amplify these women's voices regarding their personal experiences with colorism; and (3) generate culturally pertinent information that can be used to raise awareness, provide empowerment, and create social change regarding how colorism is viewed. In order to answer the question of how Black women narrate their experiences with colorism in higher education at a predominantly white urban public state institution in the South, Wiggins clearly conveyed an understanding of these Black collegiate women's perceptions by drawing on literature addressing the historical foundations of colorism, impacts of colorism on education, and the psychological impacts of colorism on perceptions of intelligence, self-worth, and self-efficacy. Wiggins used critical race theory and Black feminist thought—which combined, inform critical race feminisms—to acknowledge the participants' personal experiences, while focusing on the significant impacts of childhood trauma, overt racism, and the reality of being Black. Her study ultimately created an enhanced appreciation of Black collegiate women's personal experiences, challenges, and perspectives as they navigate a predominantly white urban public state institution in the South. Wiggins (2021) noted that as foundational understandings and significances of the impact of colorism are established, this should inspire critical discussions within academic settings to encourage the exploration and collaboration to end colorism.

Implications of CRT for future educational scholarship

While CRT has emerged as a powerful framework for understanding educational issues, it is yet to be fully realized. Scholars who employ a CRT framework most notably utilize the concept of permanence of racism and voice scholarship through counter-storytelling. For example, voice scholarship has included examining the experiences of students of color as well as the inclusion of scholars of color in theorizing space. However, the presence of an internal struggle over the materialist concerns of CRT has pressing implications for CRT scholars. Namely, it points to CRT inquiry, which has transcended from its material origins to its ideological concerns. Yet, these two forms of inquiry are inextricably connected, merely posing as two sides of the same coin. For example, while Crenshaw (1995) acknowledged identities as ideological in nature, she argued their consequences on lived experiences necessitate their consideration, in order to explicate and positively change one's marginalized condition by embracing and enacting on one's identity. In other words, although race is socially constructed and not a social fact in and of itself, the material consequence of race conveys its social significance. Therefore, challenging both the social construction of race and the enactment of

power based on race is significant. Still, the concern that scholarship in which CRT engages may never reach those who are most affected, the very populations for which CRT is meant to account for (Ladson-Billings, 1999), exists as a valid concern in which scholars must consciously engage themselves. One challenge then is in examining and asserting how ideological struggles are linked to material consequences. Harris' (1995) concept of whiteness as property, further articulated by Ladson-Billings and Tate (1995), presented the opportunity to identify (ideological and structural) processes that consequently result in concrete differences in schooling opportunities. Yet, it has been underutilized, presenting a gap for future work to fill.

Additionally, Bell's (1980) concept of interest convergence also has important implications for understanding numerous issues, including the discourse centered on Asian Americans, especially within the context of current affirmative action debates. A CRT approach which recognizes and examines how discursive practices construct, impose, and empower identity as well as shape definitions of minority, diversity, or social justice are important for understanding contemporary debates over the allocation of college-admission slots. First, it can challenge the social construction of race and further examine how particular definitions of race are privileged in certain instances and used to inform a limited definition and application of diversity that ultimately support conservative agendas (Omi and Winant, 1994). A CRT perspective can also elucidate the larger social context in which education issues are understood, explicating how international relations often shape experiences of Asian Americans and people of color in the US that ultimately support conservative agendas (Omi, 2008). For example, the perception of a peril of Asian Americans invading and overrunning higher education institutions, especially in light of recent federal court decisions involving race-conscious admissions at Harvard University and University of North Carolina, requires a critical race approach to elucidate that this perception mirrors the larger societal sentiments seen in international relations (Jaschik, 2020; Liptak and Hartocollis, 2022). Finally, CRT and interest convergence can further aid, particularly in understanding how, despite these sentiments, whiteness can be thrust upon Asian Americans (Omi, 2008; Liptak and Hartocollis, 2022) when it aids in the larger social and political interests of whites. The case of Asian Americans serves as just one example of how CRT theoretical constructs can elucidate and explicate how ideologies of race and discursive practices have real consequences and are directly connected to material interests.

Conclusion

To conclude, education scholars employ CRT to understand school inequity and educational issues while advancing the evolution of CRT in significant ways. Given its origins in and departure from critical legal theories, aimed at understanding the interplay of race, racism, and the law, a critical race analysis is appropriate for the field of education on both philosophical and historical grounds. When considering that law was used to, first, ban African Americans and other marginalized groups from obtaining education; then, institute segregation and later, repeal initiatives such as affirmative action aimed at addressing the legacy of racism, the use of CRT in education is logical if the ultimate goal is to overcome societal inequity. While these reasons alone represent a compelling case for CRT, the need for a theory which advances race as an analytical tool for understanding issues in education treads much deeper. It calls into question the ideologies and jurisprudence which informs and sustains these laws. Much like the legal scholars of color who were instrumental in creating a CRT framework, the allure of CRT for scholars in education is the possibility for liberation. Specifically, we are drawn to the idea that although schools and schooling practices (curriculum, instruction, pedagogy, etc.) are sites and tools of social reproduction, we remain hopelessly optimistic in achieving a transformative education: one that is grounded in our experiences, inclusive of our cultural knowledge, and intentionally fosters social praxis for the emancipation of marginalized communities. For these reasons, scholars of color in education find solace in the discontent, struggle, and discourse of legal scholars of color within their field, (not merely in their collective identity as people of color, but more principally) in their criticisms, yet unyielding commitment in the ideals of and belief in the very institution in which they hope to transform (theoretically, methodologically, and practically). Finally, and perhaps most important, CRT challenges scholars to interrogate their own socialization into the academy and confront their possible roles in reproducing dominant discourses. Therefore, CRT has far-reaching implications for theory, research, and practice in education. Yet, recent attacks on CRT bear close watching coupled with strategic, constructive, and bold responses to preserve its integrity and frankly, its survival, as a relevant theoretical framework in educational research utilizing qualitative methods.

Looking inward and outward

at once before and after

seeking a now that can breed futures

like bread in our children’s mouths

so their dreams will not reflect

the death of ours

Lorde (1978/1997, p. 235).

To begin an ethnographic project with a goal, with an object of research and a set of presumptions, is already to stymie the process of discovery; it blocks one’s ability to learn something that exceeds the framework with which one enters.

Halberstam (2011, p. 12).

There is no one way to “queer” research for, as queer theorists have long argued, the process of queering is fluid and liminal (Butler, 1993; Cohen, 2000; Halperin, 1995; Johnson, 2016). To “queer” research is a commitment to contradictions that recognizes the multiplicity of experiences, and troubles sociocultural, political, and historical norms and values (Corber and Valocci, 2003; Epstein, 2005; Jagose, 1996). Queering research is therefore a critical entanglement with making the strange familiar and the familiar strange (Johnson, 2001; Spindler and Spindler, 1982) in that it is omnidirectional—at once looking reflexively, as Lorde (1978/1997) argues above, while seeking to exceed (Halberstam, 2011) and abolish (Love, 2019) oppressive frameworks across scholarly dialogs.

Both queer theory and qualitative research have longstanding and complex histories. It is therefore impossible in one encyclopedia chapter to capture queer theory and qualitative research within their respective entireties. Queer theory and its relationships to communities and people who identify as either lesbian, gay, bisexual, transgender, queer/questioning, intersex, asexual, two spirit, or some combination of these identities (LGBTQIA2S++) are, for example, intricate due to multifaceted identities that exist within and across queer people, communities, and places. It is important to pause at this juncture and note three points. First, the use of “relationship” is intentional as too often when one thinks through, about, and with queerness, the idea is frequently ascribed to/with queer identities. The inclusion of the term “relationships” is to intentionally consider that one does not need to be queer to have a relationship with queerness or to be in a queer relationship. To assume one identifies within and/or across the LGBTQIA2S++ community may reinscribe the very cishetero norms and values that queer theories are meant to interrupt. Second, throughout this chapter, the author uses “queer” to broadly describe people across LGBTQIA2S++ communities as a generally inclusive term. However, while used in the spirit of inclusion, it should be noted that any umbrella term can essentialize people and falsely sew together identities that are not necessarily related to how one is identified or aligned with how they might identify themselves.

Finally, rather than using terms like “homophobia,” “transphobia,” and the like, this chapter will use terms like “prejudice” and “bias” to describe the negative, often violent, attitudes and feelings espoused by people who dislike and dehumanize queer

people. For example, the Diagnostic and Statistical Manual of Mental Disorders (DSM) in places like the United States was historically used to maintain marginalization of queer people by pathologizing sexual orientations and gender identities as disorders that, in turn, allowed family, friends, and agents of the state to forcibly institutionalize both queer identifying and queer identified people. Although the term “homosexuality” was removed from the DSM-2 in 1973, the association between queer people and a diagnosis of being “disturbed” had already caused considerable cultural damage. For example, as of 2021, there are still several states in the United States that have sodomy laws that, although not enforced, are still legal doctrines dehumanize and despoil queer energies, rendering them “illegal” and equating them with rape, bestiality, and pedophilia (Dixit, 2020). The DSM does not, however, include prejudice against minoritized people and communities as a diagnosable disorder. The characterization of “phobias” in the DSM (e.g., animal, situational, environmental, or bodily phobias are the main phobia categories in the DSM-5), overlooks how the fear of people can be psychologically detrimental. Further, phobias in the DSM are pathologized by considering an individual’s experience with diagnoses like arachnophobia, rather than considering broader sociocultural norms around spiders. The use of “bias” or “prejudice” is intended to simultaneously attend to these histories by considering how biases are at once rooted in individual experiences while acknowledging how they are enmeshed with sociopolitical and cultural norms.

Similar to the complex nature of queer theory, qualitative research is knotted (Nespor, 1997), with subsets of methodological approaches and theoretical frameworks. Further, there are varying positions and positionalities on both queer theories and qualitative research that are contextually dependent. For example, thinking about how these fields feed each other in a nation where sexual and gender prejudice often galvanize violence and encourage social and political exclusion might be a very different dialog than thinking about a nation that seeks inclusion across identities. Rather than working impossibly to not get it all wrong, as Wolcott (1994) might argue, this chapter will first trace the contours of queer theories before turning to some significant, broadly painted, dialogs within qualitative research without centering on one particular methodology. Finally, this chapter will turn to the imbrications of queer theory and qualitative research before concluding with some important implications that arise from the intersections of scholarly dialogs.

The complexities of “queer”?

In a contemporary sense, the term “queer” is rather fluid. In the English language, it can be used as a noun, and adjective, or a verb (It is important to acknowledge that queer understandings are not the same across generations, languages, and cultures. While English has been emphasized here, the author would also like to note the diversity even among English language speakers when it comes to cultural and often generational understandings of “queer.” The point is to, on one hand, acknowledge the author’s positionality as someone who, while bilingual, is writing in English and speaking from a Brown, Generation Y, and queer perspective within the United States. On the other, this is an attempt to acknowledge the often-monolithic dialogs on queerness that can come from English-normative ways of knowing, being, and doing). As a verb it can mean to look at something through a different lens; to mobilize bodies—both human and nonhuman—in ways that trouble or unsettle assumptions (Spargo, 1999). “Queer” as an adjective not only describes but can also be understood within its knotted nature of re-claiming queer-ness as both adjective and noun—or how one identifies versus how one can be identified (Johnson, 2001; Rand, 2014). Yet, the term “queer” remains generationally and contextually based in ways that are significant. In addition, as mentioned in the introduction, while queer is often a term used to broadly describe the LGBTQIA2S++ community, the use of an umbrella term can be incidentally marginalizing, reinforcing the very norms it is meant to disrupt. For example, it is not unusual to hear an individual referred to as “LGBTQ.” This assumes one individual identifies within the entire community, unintentionally flattening the diversity of experiences and perspectives across LGBTQIA2S++ communities. Queer theory is similarly fluid, wrought with potential pitfalls of essentialization, and can be understood as an engagement and entanglement with and across critical practices and dialogs. Queer theorists have—to name a few complicated and interrelated conversations—argued the necessity of queer bodies in destabilizing systems of power, queering as a way to re-consider performance and performativity (e.g., Muñoz, 2006; Sedgwick, 2003), and queer frameworks as significant in re-reading texts (Butler, 1993; Norton, 2016), across their broad conceptualizations.

Part of queer theory’s fluidity lies in the fact that some scholars who are considered queer theorists were retroactively brought into the field after Teresa de Lauretis (1991) coined the term. De Lauretis initially used “queer theory” as a provocation that was meant to unsettle gay and lesbian studies as they existed at the time. Halperin (2008) argues that queer theory was meant provoke dialogs that would encourage scholars to make “theory queer (to challenge the heterosexist underpinnings and assumptions of what conventionally passed for ‘theory’ in academic circles) and to queer theory (to call attention to everything that is perverse about the project of theorizing sexual desire and sexual pleasure)” (p. 340). De Lauretis’ call to the fields of gay and lesbian studies was, from her perspective, insufficiently answered and, barely 3 years after the initial conference where she introduced the term, she stepped back from the field, explaining that it had been picked up in ways that only reified the very institutions it was meant to resist and interrupt (de Lauretis, 1994).

Despite de Lauretis’ movement away from the field, the project of continuing to define queer theory continued. Although scholars worked to retroactively trace the contours of queer theory through its sociohistorical, cultural, and political implications (e.g., Berlant and Warner, 1995), others used seminal work to think about how the field might be shaped (see, for example, Butler’s (1990) *Gender Trouble*, Sedgwick’s (1990) *Epistemology of the Closet*, or Rich’s (1980) *Compulsory Heterosexuality and Lesbian Existence*).

Consequently, this process of tracing and shaping the field left an “undesirable and misleading effect of portraying all previous work in lesbian and gay studies as under-theorized ... narrowing the scope of queer studies by privileging its theoretical register, restricting its range, and scaling down its interdisciplinary ambition” (Halperin, 2008, p. 341).

Through the process of de- and re-territorializing the field of queer theory, a space for critique of the field itself among queer theorists was constructed. These critiques included scholars considering the voices present and those (un)intentionally silenced. This included dialogs on genders in their multiple forms and expressions (e.g., Halberstam, 1998), sexual orientations (e.g., Dilley, 1999), races (e.g., Johnson, 2001), and, later on, intersex bodies and beings (Morland, 2009), and dis-abilities (McRuer, 2006), to name a few. The field also wrestled with its dis-connection with queer activism. Activist groups, from the Mattachine Society in the United States (established in 1950), to the United Kingdom’s Stonewall (established in 1989), to Italy’s Circolo di cultura omosessuale Mario Mieli (established in 1983), to Iceland’s Samtökin (established in 1978), among others, existed long before queer theory was codified in academic circles. This scholar-activist split was, as scholars have argued, potentially detrimental to early policy work across global and local contexts (Rand, 2014). Further, queer politics tend to be organized around the narrow notion that queer activism was a direct response to Reagan-era responses to the HIV/AIDS epidemic.

In the United States there is truth to the galvanizing response that Reagan-era politics created in queer movements. However, it is equally important to recognize radical global movements against racism, sexism, and ableist ideologies that were central to queer activist work that has also become central to scholarly dialogs. As Cohen (2019) argues, forgetting this can cause an erasure that “inhibits our ability to know what happened before us” (p. 141). Cohen continues by explaining there were, for example, several Black radical individuals like Audre Lorde, Marlon Riggs, Cheryl Clarke, and Pat Parker who were active in documenting, fighting, and providing organizational structure to perusing liberation and drawing attention to anti-queer inequities. The work of these activists has also become central to the theorization of queer theory as it exists in contemporary scholarly conversations (e.g., Mayo and Rodriguez, 2019; Pinar, 2012; Rodriguez et al., 2016).

The troubling of essentialist and limiting notions within the field has been significant in how scholars have attended to both political implications of the field and the broader cultural impacts of the field. Specifically, there has been an attention to how queer theory has been defined, mapped, and de/territorialized within the academy and its broader communities (Talbot and Steinberg, 2000). This had led to more complex theorizations of intersectionality (Crenshaw, 1991; Jones and Abes, 2013) within the field. For example, in 2001, E. Patrick Johnson critiqued queer theory for suppressing dialogs of race and class. Johnson proposed “quare theory” as one way to actively attend to the political power inherent in racist and anti-queer spaces and places. Similarly, decolonial and indigenous scholars have proposed a queer-decolonial lens (e.g., Driskill, 2011; Pereira, 2015; Singh, 2017) as a way to create and deepen a presence of GLBTQ2 people and communities in queer theory and broader policy dialogs. Finally, scholars attending to thin-normativity have used Sedgwick’s (1993) call for queer theory to provide a “spin outward along dimensions that cannot be subsumed under gender or sexuality” (p. 9) to include voices on fat-studies, a metaphorical queering of the fat body (e.g., Pausé et al., 2016).

While these movements represent a sliver of the critical conversations within the field as it continues to touch and be touched across scholarly work, it is important to note that inherent nature of the field continues to open up spaces of possibility within critique and re-thinking what it means to be a “queer theorist” and engage in queer theory. This chapter will now turn to qualitative research as it is entangled with queer theory before concluding with implications for the field(s).

Queering qual: the re-mapping of research

Broadly, the field of qualitative research has worked with/in tensions, hesitations, and contradictions (Denzin and Lincoln, 2008). Within the field, researchers have attempted to decolonize the process and presentation of collecting and disseminating empirical data (Smith, 2013) while attending to issues like the inherent racialized (e.g., Solórzano, 1998; Steinberg and Cannella, 2012), gendered (e.g., Ribbens and Edwards, 1997; Rogers, 2020), ableist (e.g., Annamma, 2016; Lester and Nusbaum, 2018), linguistic (e.g., Heigham and Croker, 2009), and heteronormative (e.g., Spencer et al., 2014) ways of being, doing, and knowing that were normalized early on within qualitative research. In addition to these internal tensions, qualitative research also has longstanding histories of interrupting norms centered on quantitative research that rank numerically driven research as superior, often arguing that it is a more “valid” form of data collection and dissemination of ideas (Behar and Gordon, 1995; Denzin and Lincoln, 2008).

Much like queer theory, qualitative research had a relationship with queer scholars, queer communities, and queer/d ideas prior to the field being named and recognized across academic disciplines. For example, the 1990s includes a rather extensive list of scholars who were working with/in queer scholarship (e.g., Britzman, 1995; Kumashiro, 1999; Jagose, 1996; Lather and Smithies, 1997). While these scholars might not have necessarily identified themselves as “queer theorists” at the time, their work has been identified by the field as significant in forming and informing the work of queer theory and qualitative research. Similarly, as with all qualitative research, queer(d) narratives are often analyzed though work that, while not qualitative inquiry, speaks to and across fields of empirical research. This is significant in that queer theory informs qualitative researchers in the same way that qualitative research can inform queer theory. This reciprocal relationship between queer theory and qualitative research is central to, as Kincheloe and McLaren (2011) argue, unsettling marginalizing conceptual frameworks through the nexus of critical theories and qualitative research. Queer theory can, for example deconstruct ideas and ideals within qualitative research while qualitative research can ground queer theory in material concerns of cishetero oppressions.

One important factor to the growth of queer voices and narratives in qualitative research lies within the increased visibility of LGBTQIA2S++ people and communities across contexts (Sears, 2005). Although telling vulnerable stories is always a brave act, there is something significant to having access to queer experiences and, especially for researchers to have those narratives valued across academic spaces and places (Levy and Johnson, 2012). This is not to say that those who do queer qualitative work do not still face oppressions in the form of gaslighting (Wozolek, 2018), being dismissed (Allen and Rasmussen, 2015) and facing normalized dehumanization (Kessi, 2018) across higher education. Yet, the ground that forefolx paved in terms of liberatory policies and practices has made studying and reporting queer narratives through qualitative research far more accepted and, in certain contexts, highly valued, than it was when queer theory was in its infancy.

Queer theory as it is related and, for some scholars, integral to qualitative research is not as much a methodological turn but an attention to how traditional methodologies can be queered. For example, Lambevski (1999) argued that researchers are not often transparent about the tensions of personal experiences and identities as they intersect with one's research. While this might seem as incredible in a contemporary era where situating oneself is expected in qualitative research, and vulnerability has become a well-trodden dialog (e.g., Behar, 1996; Geertz, 1973; Rosaldo, 1993), it is significant to recall that despite white male privilege as an academic, scholars like Humphreys (1970) were unable to write about their own sexuality in their research. Although, as Plummer (2008) points out, despite the absence of identity in Humphreys' work, there is a footnote about the taste of semen so, as many queer authors do, Humphreys leaves a trail of breadcrumbs toward queer understandings and identities. The work of scholars like Humphreys paved the way for others, like Miller (1998) whose part qualitative research, part autobiographical work is intensely personal as he discusses gay culture in Broadway. Others, like Weinberg's (1995) edited collection that focuses on bondage, discipline, dominance and submission, and sadomasochism (BDSM) culture and, while now slightly dated, set the stage for sociological rather than psychological conversations about kink-positive culture and identities (e.g., Carlström, 2019; Fennell, 2018) through qualitative research and other significant theoretical frameworks.

Along similar lines, queer theory offers a critical lens through which foundational methodological processes are carried out. Regardless of one's identity, or how they are identified, using queer theory as a lens through which one conducts qualitative research can, and to some degree should, deeply impact a method. Wells et al. (2012), use fieldnotes as but one example of the effect queer theory might have on ethnographic research. "Queer theory," they argue, "asks the researcher to put power relations ... in the forefront of her mind not only during analysis, but also during data collection. The fieldnotes, then, should include information about actions, dialogs, events, and so on in relation to this axis of social relations" (p. 121). Although the authors foreground sexuality, it is important to understand the move in contemporary queer theory to, as Sedgwick (1993) argues, allow critical queer analysis to "spin outward along dimensions" (p. 9) to include queering qualitative inquiry across its methodological frameworks and processes.

It should be noted that while it's significant to have representation in terms of ideas and voices, there are times when identity politics have been a detriment to who can collect queer narratives and who is seen as a person who can theorize them ways that are recognized as "valid." For example, Youdell (2009) illustrates this tension between perceived researcher identity and local actors in her article "Queer Outings" in which she discusses a context where students read her involvement with a boyfriend as a claim to heterosexuality. Although bisexual, and a person who rejects the idea of the closet, she recognized how her "passing" as straight impacted her research and relationship with participants. Other scholars have argued that prevalent identity politics that dictate straight researchers are unable to participate in anti-normative scholarship detrimental (Allen, 2010). Although, to be clear, it is important in contexts like Youdell's research for students to understand queerness as normal, and researcher identity matters, this brings into focus how scholars might take up Britzman's (1995) dialog to "stop reading straight" in ways that both acknowledge the significance of identities while resisting a kind of identity politics that can reinforce the very kinds of exclusion that queer theory is meant to interrupt, particularly as it intersects with qualitative research.

It should be noted that while Britzman called for scholars to attend to what it might mean to "read straight," this does not mean that cishetero identifying people cannot engage in queer theory, qualitative research done through a queer theory lens, or with queer identifying participants. One can argue that contemporary researchers often find themselves in a conundrum driven by identity politics. Qualitative research has histories of marginalizing people and communities as, historically, straight-presenting, white people would exoticize and Other people of color, economically disenfranchized people, queer communities, and the like. One only needs to reflect on early ethnographic work to understand how othering was normalized and, just as importantly, how ethnographers like Geertz (1973), Behar (1996), and Agar (1996), among others, attended to these normalized forms of dehumanization in their research as an attempt to ethically (re)orient qualitative research. Inherent in these dialogs are questions of voice and transparency that are critical to qualitative research and, when implemented, can be considered a way of queering qualitative research and scholarly orientations that caused harm across people and contexts (Jones and Harris, 2018). This does not mean that one's identity need to align with the participants in a study but, rather, like all strong forms of qualitative research, that one's positionality should be clear in their writing, regardless with whom and where data was collected. To be clear, this is not a call for people to out themselves because it is important for any person to be able to reveal facets of their identity on their own terms. It is, however, a call for transparency about one's ethics and positionality.

While the idea of queering qualitative inquiry has underscored the significance of how people and communities are represented in research, it is important to remember that queer theory exists as a theoretical framework that acts as a lens through which qualitative research is carried out, analyzed, and presented. Scholars have used this lens as one way to foreground the political (Plummer, 2008) and to refuse traditional methods to propagate a "certain disloyalty to conventional disciplinary methods"

(Halberstam, 1998, p. 10). Though used frequently as a textual turn in analyzing films, literature, television, and the like (e.g., Doty, 1993; Sedgwick, 1985), others have used queering methodology as a way to subvert traditional qualitative scholarship that often silenced LGBTQIA2S++ people and communities—a way to galvanize queer folx and refuse ideals of fixed identities (Gamson, 1995; Quinn and Meiners, 2009; Sykes, 2011; Whitlock, 2013). What queer theory offers in terms of political ideas and ideals is yet another way to reject modernist tendencies to position the researcher as detached and objective (Wells et al., 2012). This is not unlike other forms of qualitative research in general and, specifically, ethnographic research and other forms of narrative inquiry that acknowledge subjectivities as central to qualitative inquiry as a whole. The queer ethos in qualitative research is therefore defined by (re)imaginings, (re)orientations, and challenges to dominant discourses.

Finally, queer theorists who work through qualitative lenses in general, and educational research specifically, have argued that queer theory as it intersects with qualitative research should emphasize the importance of destabilizing norms and values (e.g., Jagose, 1996; Rodriguez and Pinar, 2007). However, there is a tension between educational research as a way to understand, recognize, and affirm queer youth experience, and the essentialization that often happens when data is deemed generalizable (Chang, 2005) across contexts and experiences. To this point, Wells et al. (2012) argue that researchers often “actively, although unknowingly, engage in normalizing discourses that structure their social contexts ... the social therefore arises in people’s activities and through the ongoing and purposeful concerting and coordinating of those activities” (p. 118). Although it is significant to trouble the sociocultural practices that have normalized the closet (Kissen, 2002; Sedgwick, 1990), it is equally as significant that qualitative research does not use the space to reify normalized views of queerness or reinforce binaried ways of being, knowing, and doing.

Conclusion: what’s next?

Queerness can be understood as a space of possibility (Edelman, 1998; Weiss, 2016). To queer ideas means to engage critically; interpreting moments, thoughts, data, bodies, and the like from multiple directions and perspectives while rejecting traditional norms and values. It is troubling of sorts (Butler, 1990) that deconstructs binaries in and across cishetero patriarchies. Yet, queer theory is not siloed. It emerges with and from seeds sown in fields like Black Cultural Studies (e.g., Mercer, 1994), decolonial studies (e.g., Pérez, 1999), critical race theory (e.g., Harper et al., 1997), and indigenous studies (e.g., Driskill, 2011), among others. To engage with queer theory, then, does not mean one must identify with or have personal histories with queerness. Nor does it mean that a researcher is positioned within an “either/or” of theoretical frameworks. Instead, the richness of queer theory, like the richness of strong qualitative research, can exist in nested and layered identities and curiosities that are ethically attuned to queer lives.

The relationship between queer theory and qualitative research is significant for at least the following reasons. First, the tension between queering qualitative inquiry and not allowing such work to (re)create binaries can be understood as the very foundation queered qualitative research. Second, and related to the potential pitfalls of the first point, queer researchers have used their work to call for and create contexts that foreground equity and access (e.g., Love, 2019; Mayo, 2006; Tierney, 1997; Wozolek, 2018). While this orientation to action, what Lather (1986) discussed as catalytic validity, or what Wells et al. (2012) discuss as empowerment-as-action, has its limitations, it is significant in terms of how theory and practice can move not only the field but broader sociocultural and political norms. Third, queer theory as it relates to qualitative research is yet another tool for researchers to use in terms of reflexivity across researcher and participant identities and they are formed and inform their imbricated contexts.

Queer theory and qualitative research, as they exist separately and within an entanglement, continue to be challenged by forms of oppression that exist both within and outside of their respective and interrelated fields. There is however, as scholars have argued, always greater in-group than between group difference (Gershon, 2017; Tatum, 2003; Varenne and McDermott, 1998). Such differences tend to be sorted through oppression that helps gain cultural capital (Bourdieu, 1993; Freire, 1970; Wozolek, 2019) and maintains lines of power (Foucault, 1978). Within queer communities, this tends to be a focus on, for example, sexualities over genders or the silencing of queer Black, Indigenous, people of color in ways that narrow the field rather than allow it to exist as a pluralistic bloom space (Stewart, 2010) of possibility. As researchers continue to use queer theory and its interrelated narratives to disrupt anti-queer norms and values through qualitative research, the field itself must continue to disrupt the very lines of oppression that reinscribe marginalization. Such forms of oppression are often born within and across in-group narratives as they are imposed through out-group messages, politics, and cultural ideals. Similar to dialogs within critical race theory (e.g., Bell, 1995; Delgado and Stefancic, 2017) and critical race pedagogies (e.g., Freire, 1970), both in- and out-group marginalization only serve to reinforce power structures in ways that will allow oppression to continue largely unabated.

In addition, queer theory as a theoretical framework for qualitative research must also think critically about making sure that queer narratives themselves are diverse, not just in terms of sociocultural precepts but in terms of representations of the many conditions under which queerness exists. There are, for example, many necessary queer narratives about exclusion, silencing, and violence that happen when White, cishetero, and patriarchal ideas and ideals collide with queer ways of being, knowing, and doing (e.g., Brockenbrough, 2018; McCready, 2010), there remains a need for more narratives about queer excellence and accomplishment (Rosenberg, 2018).

Queer theory is certainly far from the only way that qualitative researchers can resist and refuse objectivity. However, it continues to be a powerful tool for researchers to explore spaces of possibility that can abolish oppressive norms and values that are present not only in everyday experiences but also throughout the academy (Allen, 2010; Dilley, 1999; Gilbert, 2014). Critical queer theory's attention to power and politics in terms of silencing across contexts continues to be one way that these fields are significant in creating and maintaining equity and access (Chang, 2005) to address normalized oppressions. Returning to the quotes by Halberstam (2011) and Lorde (1978/1997) that opened this chapter, queer(d) qualitative research is therefore significant in "looking inward and outward ... to seeking a now that can breed futures" (Lorde, 1978/1997, p. 235) while letting go of "presumptions [that] block one's ability to learn something that exceeds" (Halberstam, 2011, p. 12) the past, present, and projected futures that we have, do, and have not even begun to imagine.

Acknowledgment

My gratitude to my forefolx—those who came before me and not only whose work has been central in my intellectual growth but to those whose bodies and beings in the academy have made my ways of being, knowing, and doing as a Brown, queer woman possible in and across academic spaces and places. In addition, to the contemporary scholars who continue to be my chosen family, my continual appreciation and love.

What is that, silent as a fox, sneaking through the research woods? Can't really tell. Could be fox. So hard to define, yet fundamental to the methods of inquiry. Seen differently in different contexts, for different purposes, and yet the favorite of doctoral students, at least in certain fields. Not really foxy, but an approach to inquiry with promise of being vivid, protective, and valid, capturing the movement and complexity of the case and its habitat.

The disciplined study of cases in education

Education is a phenomenon resounding wonder. The wonderful doesn't hide the dread and boredom and discrimination of classroom or lifelong learning, but the puzzlement of the unknown (and unknowable) is ever a challenge. It is the mystery of metaphors and minus numbers and microbiologics that ever keeps our minds off balance. Education is an everybody's venue of inquiry, charming and desolate. With method or not, we grasp at meanings, seeking to find a fit for the oncoming strangeness. The strangeness is often a something, and we need to know that something better. It can be a case, a single case—stirring our wonder—and before test time or deadline, we need to know it better, a case to be studied.

Belonging to a discipline or not, the case study is usually the study of one thing. For the uniqueness or generality, we seek to understand more about that thing. Sometimes that thing is compared. Other times not, but we do not primarily study a case to understand other cases. The case is a bounded system, a special something to be studied, an entity such as a child, a teacher, a classroom or a program. A phenomenon or a relationship may also be studied indirectly, but the case is the entity to be studied directly. Take for example, a manager, as the case. As with other cases, the manager has activities, problems, decisions, relationships, all of which may need to be looked into for a study of the case. The particular case has, in some ways, a unique life, although many parts of it may be ordinary. We study the ordinary but especially the unusual. The case is something we do not sufficiently understand, and studying it means we give it special care.

Case study is a method of inquiry, or a collection of methods, used to dispel and to expand the wonder of understanding the individual case. Sometimes because we have questions, making the case study instrumental. Other times because the case presents itself to us with an intrinsic value, we call that an intrinsic case study. Either instrumental or intrinsic, a case study in different places goes by different names (Feagin et al., 1991). Sometimes it's a diary, sometimes a transcript, a course file, sometimes an obituary. Biographers call a case study a biography, cartographers a map; all of us call a history a history. It's a history of something, a history of a case, brief or unending. There should be no pressure on us all to call it the same thing. Or to define it the same. In a distinguished career, sociologist Howard Becker (1992) regularly studied cases, but preferred to call his case study, "fieldwork." Lots of tabs, still, the discipline of case study, as a scholarly research method, calls for us to recognize some important descriptors to be selected and certain happenings to be recorded, so as to understand the case better.

Much scholarly study is aimed at theorizing, generalizing, to understand causality and interdependence. That is not the strength of case study, although it happens (Yin, 2013; Ragin and Becker, 1992). Surveys and experiments are mainly for the purpose of comparison and explanation, sometimes found useful in case studies (as in the example of the Veterans' Regional Center, later in these pages), but understanding an individual case, even a case inclusive of many places and times and people, concentrates

more on the *activity* and *context* of that one case. A case cannot be well understood without some comparison and sense of agency, but the usual purpose is to come to better comprehend that designated case, that bounded case.

Case study is sometimes thought to be more on the side of personalizing an inquiry, and a tally might find it so. But personalization is not a definitive characteristic. Personalizing does not necessarily make a study a case study. It could, for example, be an autoethnography or narrative without being a case study. For a case study to be a case study, there needs to be a case with clear boundaries and issues, as well as an interaction with a context.

An issue is a matter of contention which is of special concern or importance. In case study, an issue has to do with the functioning of the case, particularly reflecting one or more of its purposes, an exercise in management by those in control. Certain choices or actions are taken, with uncertainty as to the implication or outcome, with different effects on different constituents likely. Here is a visualization that may help.

Personalization by extending intimacy and compassion into the study, may open important facets of understanding, but may threaten the intersubjectivity of the study. In case studies, intersubjectivity is a matter for researchers to negotiate with their audiences, being informative as to proximity of observation and depth of questioning. Case study can be a ground for compassion but the method tolerates indignation and intrusion if they better get the story told (Merriam, 1998).

Observation is a high priority method for the case researcher, often more important than interviewing or document examination. The quality of observation depends on discipline and repetition. One needs to think through, in advance, some of which may come to pass. One needs to be part of the context of the case more than once. Classification of issues and unfolding insights about those issues is needed to tease out subtle tendencies. Without deep involvement, not meaning participation but meaning pondering, one cannot notice nuances and tease out meanings. Much of the budget may be consumed bring in watchful eyes and note-taking laptops, resulting in little remaining for persons and sites and occasions to be recorded. The generality of aspects within the case (everywhere true? always true?) require multiple kinds of evidence, often relying on the observations and recollections of others than researchers. Existing documents, photos, recordings can reward a diligent search. This is not a case of law: evidence is defined not only by the observer, but by the reader, given thoughtful help and cautionary advice by the author. So case study uses a kaleidoscope of approaches, from narrative to ethnographic, and a kaleidoscope of methods, from observation to interviewing. Any style of inquiry may be used—it should fit well the audience and purpose of the study (Stake, 2005).

That may be giving too much leeway to the researcher. Just as there are questions of validity in studies relying heavily on measurement and statistical analysis, validity is an issue with case studies as well. Triangulation is the term used by many researchers to draw evidence from different vantage points to show accuracy of data and strength and weakness of the finding. The data in all studies can be interpreted in multiple, even contradictory, ways (Creswell and Poth, 2018). And the researcher has an obligation to search how the representation of the case can be differently interpreted and misinterpreted, and to say so in the report. In the case study example (several pages ahead), the reader might conclude that central office (federal) administrators were insensitive to regional office communications with veterans, and perhaps the researchers insufficiently looked into evidence of that perception.

The Holy Bible and Koran are case studies, possibly long ago at risk of being turned down by a doctoral committee and the journal editor. Truth and faith need to be part of the review, and so with other accounts of experience. The readers have their own affairs to keep in order, advocacies, reputations and page limits, but stories need to be told, and meanings questioned. Mistakes will be made and beliefs pondered. Case studies, spirited and perfunctory, are in little danger of being superseded. But in an age of free speech and political misinformation, a discipline of inquiry works against amusement and persuasion (Kemmis, 1980).

Case study design

Size

A case study project or its report can be large or small. The study can be personable or austere, chatty or scholarly, activist or dispassionate. In research circles, it is likely to be more respected when dealing with scholarly relationships and circumstances (Geertz, 1973). Political content such as street protests can increase the report's circulation. (MacDonald et al., 1982). But an hour of pondering the case will sometimes be the right measure.

Choosing cases

For the teacher, the program evaluator and the auditor, their cases are usually known or assigned in advance. Their cases often have been of interest before any formal study begins. For educational researchers, case studies usually require cases to be chosen. At the outset of a case study, sometimes a phenomenon such as discrimination or on-line testing is identified—the cases are opportunities to study it. Understanding critical phenomena and emerging problems may depend on choosing the cases well. Even when the cases are decided in advance, the researchers may need to select persons, places, events, and other “particulates” to observe.

Types

Many have categorized case studies (Hamilton, 1980; Schwandt, 2000; Sjoberg et al., 1991; Stenhouse, 1979). Stake (2005) identified three types. An *intrinsic case study* is undertaken because the researcher wants better understanding of a particular case. Here the case does not represent other cases, nor does it need to lead toward theory. It does not illustrate a particular feature or problem. An

intrinsic case study is often chosen because of its particularity *and* ordinariness. The case itself is of interest. It is cared about. It sticks out as the one to study. The second type is an *instrumental case study*. This type provides insight into an issue with an aim to generalize, to transfer insights to other contexts. The case is of secondary interest, it plays a supportive role. It facilitates our understanding of something else, again maybe discrimination or on-line testing. And third, collective case study, also called multiple case study, encircles a number of cases, separately and together, in order to *investigate* a hypothesis, gathering, phenomenon, or condition. Here, researchers strive for a common understanding, or they want the case study to contribute to the development of theory (Gerring, 2017).

Narrative study

Case studies and narrative go hand in hand. Case studies are represented through thick descriptions using narrative vignettes to convey experiential data, sometimes visuals, but also statistical data, if relevant. Narratives situate the study and its experiential data. Significant events, times and places and any memorable contexts serve to make many case reports easier to understand. A strong story is the vehicle in many biographies, histories, and developmental records. Interviews often serve well in data gathering. Dialogic presentation, conversational format, is popular with many case researchers (Smith, 1994; Clandinin and Connelly, 1999; Silverman, 2000).

Issues

A research case study does not seek to understand a phenomenon in order to control it. Seldom to predict or find the basic truth in it, such as an essence. When we study a case, we are sensitive to learning about its discrete units and their relationships. They show us the pathway to understanding issues that are at stake. A case study is not so relevant when we want to understand broad information questions such as “How were these programs implemented?” and “Who cares for most of the elderly?” Case study leans toward other questions, such as “How have they tailored this particular care to women who home-school their children?” or “What happened to the elderly when their residence home (the case) participated in a community-outreach program?” Case studies are organized around *issues*. Issues are complex, situated, problematic relationships. They are themes, arguments, trade-offs. We cannot know all the issues before we enter the context of the case. We gradually learn to formulate better questions, driven by issues. Issues invite attention to ordinary experience but also to the language and understanding of the common disciplines of knowledge, such as anthropology, economics, political theory, and literary criticism.

Many qualitative case researchers orient to complexities connecting ordinary practice to the abstractions and concerns of academic theories. This dialectic connection is present in the single case study, but does not replace it as focus. There is a fine line and tension between practice and theory, needing the researchers’ attention. The themes and issues used to organize the study may or may not be the ones used to report the case to others. Observing and analyzing work are different work from presenting the case report. At the end, it may be the anticipated issues of readers that will structure the report (Becker, 1992).

Activities

Usually, researchers need to find out firsthand what the case does (did)—its activity, its functioning. Sometimes the most direct answers come from observing the actions of people, the operation, if in the context of a program, or asking those who saw it (Erickson, 1986). This includes people as cases. Almost always, the case’s activities are expected to be influenced by contexts; understandings need contexts. Therefore, contexts need to be studied and described, whether or not evidence of influence is to be found. People simultaneously experience many things. The researcher lets mind and eye scan a large number of happenings, variables, and contexts, and makes tough decisions as to what to dig into.

Triangulation

Case researchers are a heterogeneous lot, but most are disposed to tell the truth, even though that is not the purpose of case study. They selectively choose which (narrative) truth to tell, but they choose not to deceive and seek redundant confirmation of their main interpretations. By observations that approach from three or more directions or data sources to support their claims, they offer confirmations. They call it, “triangulation.” They mean pretty much what measurements specialists mean by “validity” (Campbell, 1975; Maxwell, 1992).

Humanistic study

Many intrinsic case studies have a humanistic leaning, but it need not be. Particularity or ordinariness does not immediately mean we pay attention to human experience, relationships or issues of empathy and compassion. A humanistic lens would highlight human welfare and progress, dignity, dialog, openness. Even when a case study is not seen to be “humanistic”, we can still look at what happens when people are in play, what human activity is going on, and what meanings unfold in the process.

An example of case study: reader focused writing program

For these pages on case study, we have chosen to include a half-shortened case report of a Reader Focused Writing program as an example (Stake et al., 1997). As an example of an intrinsic case study used in an administrative situation, it is the report of a formal, contracted evaluation of a training program run by the US Veterans Benefits Administration, a federal agency. Not much can be learned about that particular training program from just one short report. But something can be learned about the method from a single case study. The purpose here is to illustrate choices, hazards, and opportunities in doing a case study for institutional purposes. Much case study research will be with cases of persons, but any program or initiative can be a case to be studied, and the case study below should help us understand organizational complexities.

The case (here an evaluand) was a special all-states program to improve letter writing to veterans regarding housing, education, and other earned benefits. The evaluation was conducted for the Veterans Benefits Administration by a University of Illinois CIRCE team during the fall of 1997. A four-member team of evaluation specialists was led by Stake et al. (1997). In addition to Indianapolis, evaluative case studies were conducted at St. Petersburg, Boise, Baltimore and Denver. Five of the fifty regional offices were chosen for data gathering, and each was treated as a case, so the collection could be called a multiple case study (Stake, 2006). The report was a report on the quality of the training nationally. In addition to these five case studies—making the report a multiple case study report—national data gathering and analysis included veteran interviews, a staff survey, pre- and post-training letter comparisons, a regional director survey and administrator interviews. The several tasks are shown on the next page. The responsibilities of team members are indicated by the sectors and the case study sites.

The Reader Focused Writing program was ordered by Congress because VA letters to vets are periodically complained about for being inconsiderate, incomprehensible and legalistic. Congress ordered the VA to fix it. In this case, 656 participants took a seven-day satellite training to improve their letter writing to veterans. From the case we learn about the tension between adhering to protocols, “indicators of production”, leading to not so good letters, and what needed to change to produce a better letter. Trainees were torn between doing what was required, or doing what was needed, at the expense of productivity—a struggle that we all know so well and want to escape from. Here, we already notice several issues, such as the tension between needs for communication and staff time available for communicating.

Indianapolis Regional Office, Robert Stake (Stake et al., 1997)

Upstairs on the third floor of the Federal Building, I inquired about services to Indiana veterans. The workers there were aware that from time to time the federal Veterans Benefit Administration was accused of writing incomprehensible letters. They knew from experience that over the years, many letters had been bad, filled with legal jargon and bureaucratic syntax. Furthermore, they knew that they were part of a political context. But when they discussed their work, they spoke consistently without reference to the media, Congressional oversight, or what the public thought of them. There was a world of veterans, many of whom they had talked to on the phone, a world that included loan agencies, hospitals, and colleges. They referred often to the Central Office in Washington, but in organizational terms, not political.

The station

The VBA Regional Office in Indianapolis provided services. For disability compensation, pensions, vocational rehabilitation, and backing for home loans. Educational and insurance benefits were handled at St. Louis and Cleveland, respectively. As the division names imply, these services are quite different, and specialized within, so that the responsibilities of different workers ranged greatly from room to room across the station. Staff size was about 145, down from a high of 200 three years earlier. Loan Guaranty currently had 30 positions; Vocational Rehabilitation and Counseling, 11. What had been the largest group had become larger, with 81 positions, as Compensation and Pension merged with Veterans Services. C & P was where adjudicators and rating specialists acted upon claims for support due to physical disability resulting from military service. The reorganization brought with it the expectation that more personal communication practices, via telephone and face-to-face counseling, would reduce the heavy load of adjudication letter-writing (although paper trails would not disappear). The local work in Loan Guaranty was changing as Indianapolis became the national center for a portfolio loan program. Down-sizing (called “right-sizing” by some) meant not only a diminution of time available to handle a claim but an increase in claims handled at a national rather than regional center.

The director of this Regional Office was Dennis Wyant, heading the office since mid-1994 after many years in the Central Office where he had been national director of Vocational Rehabilitation and Counseling. Wyant held a doctorate in Education and was a certified rehabilitation counselor. Despite being legally blind, Wyant kept an eye personally on what was happening around the station. He was a “people person,” a “problem-solver,” neither confrontive nor authoritarian. He heard well what his chiefs and assistants had to say about running the programs. He expressed strong support of Reader Focused Writing as a step in the improvement of services to veterans.

Claims for benefits are made by veterans filling out forms. Most veterans have made contact with one of the service organizations, the American Legion and Veterans of Foreign Wars, for example, and many first encounter VBA with a form already filled in. Some requests are taken by telephone or over the counter, but quickly forms become the currency. Some forms are supplemented with records from doctors or campus admissions offices or county offices and such. The evidence is reviewed and a reply prepared.

For a disability compensation claim, an adjudicator will recognize which on the menu of computer letters should be called up, and by using Microsoft Word and PCGL (Personal Computer Generated Letters) and by filling in blanks, modifying language, and attaching forms and pamphlets, compose a reply to the claimant.

A quality assurance review annually examines a sample of cases from the compensation and pension files, 106 were selected for 1996, of which 90 were reviewed by a federal team. Attention is given to the appropriateness of findings and not to the appropriateness of the communication. At Indianapolis, for a while, different divisions were conducting their own quality assurance operations but reports are no longer required and the practice waned.

RFW training

On September 24, 1996, Wyant wrote to his division chiefs informing them of the Reader Focused Writing schedule as follows:

We are nearing our scheduled time for Indianapolis to receive RFW training. Each RFW Tools Course consists of seven sessions; approximately 3 hours each of core instruction and a 2–3 hours follow-up approximately 6–8 weeks following the class. The 3 hours per day includes 2 hours of broadcast instruction plus 1 h of class. Exercises and practice. Since we have eight keypads, we can train eight during the morning and eight during the afternoon.

Such lengthy all-staff training had not happened previously at the station. Opposition to the plan among the chiefs and among the workers was considerable, voiced as putting too much strain on the workload, but also with skepticism that this professional development workshop, “as always before,” one trainee said, would be anything more than consciousness-raising. It also was recognized that, for most of the participants, letter-writing to veterans was not a large part of their job description. But opposition melted with realization of the generality of the communication principles and the appeal of the composition techniques, warmed also by opportunity to work on interesting tasks with staffers from other divisions and by the high quality of the broadcasts. In retrospect, essentially all participants considered the training relevant, practice-changing, and personally upgrading.

For 2 hours a day in a corner of the station’s large conference room, the eight participants for each session watched—via satellite screen—Melodee Mercer, a loan guarantee specialist in Philadelphia and member of the VBA communications task force coaching the RFW and interacting on touch pads. “On page 48 of your manual, in the letter from Timothy Morrell, what implied questions can you identify? Your light is on, Frank at Detroit, what questions are implied in his letter?” The individual touch pad connections failed often, but ordinary phones then were substituted. The third hour was used for group activities. The exercises were well developed, thought-provoking, especially in that they gave the specialists opportunity to see how co-workers in other divisions resolved content problems. No further broadcasts were scheduled and even the six-weeks-later sessions disappeared.

Obstacles to implementation

One of the primary findings from our fieldwork is that there was not a close match between the training and the actual work at Regional Offices. It has already been mentioned that the work is diverse and specialized, yet the training was the same for all participants.

Regional Office staff members who participated in VBA training in October 1996, were unanimous in considering quality of letter-writing to veterans an important issue and that writers should strive to orient more to the veteran’s needs. All of the 29 but two said that this VBA approach made sense to them and all but three said that VBA was *not* making too much of a fuss about improving letter writing.

In the interviews as well as in the surveys, it was apparent that the staffers supported a continuing effort to improve letter-writing. An interviewee said.

It has been a long time since we have taken a hard look at letter writing and communication skills in general. Some letters we send out are confusing, legalistic. The Agency as a whole needs to provide the legal angle, and that still is the dominant attitude across the Agency. We are not allowed to advocate for the veteran or to gather information to advance his claim. RFW training is the first time the Agency clearly provided a pro-veteran view. It was long overdue.

In interviews with six of these respondents, it was also apparent that they felt that the quality of letter writing had improved considerably in the last several years. When asked why, two or three said, “The main reason is that the standard computer letters that we draw from are much better than they were”. Twenty-four indicated they had applied RFW ideas to their own work, four of those said “often.”

We asked these 29 trainees what portion of their work time they presently spent writing letters to veterans. Nine of them indicated they did not do that at all and the median for the group was doing it only 5% of the time. Only three of them indicated that they spent half their time or more writing letters to veterans.

In two separate ways, we asked them the average amount of time in the last year spent on developing RFW skills. The median was 1–2 hours per month. Almost half of them had participated in earlier VBA efforts to improve letter writing. About a third of them had once had a formal writing-improvement course. When asked about the need for inservice training of all kinds, the median of the group responses was that 4 h a month should be set aside.

As to the training activity, 26 of the 29 checked that it was well organized. The same number said they learned much about better letter-writing. Just over half said the videos and materials were of high quality, five said low. About half of them said that the quality of the contribution of the on-site instructor was low.

As to implementation, 20 indicated that it was impractical to implement RFW in the ways illustrated in the course, apparently meaning that there were just very few occasions for start-from-scratch letter writing, and too little time to do it. When asked if the organization of the Regional Office had changed in any way to support RFW, 17 said “no” and another 11 said they didn’t know. In follow-up, they assured us that the officers had clearly indicated their support for RFW letter writing but, as they saw it, the organization had not changed to make it happen, and most did not see ways that it should change.

When asked if simpler letters trying to deal with a complex situation sometimes steer the veteran wrong, chiefs and workers alike said they could not identify cases of that happening. One added, “The complex information is in the attachments and we always tell them how to ask for more information.”

One thing apparent in discussions at Indianapolis was a perceived mismatch between the training as designed and work methods and workload of the staff. The training apparently did not sufficiently acknowledge the diversity of communication responsibilities within VBA or sufficiently point to the generality of the RFW approach for communication in general. Two suggestions arising again and again were that in their own communications by letter, the Central Office should exemplify Reader Focused Writing and that the computer letters and the PCGL programs should be further upgraded along RFW lines.

The image of service

Even under careful probing, the staff of the Indianapolis Regional Office revealed a strong work ethic and a sincerity in being of service to Veterans. But they also were careful to maintain a good public image. They were highly aware of the low regard many citizens have for federal employees, and they themselves decried bureaucracy and political motive, for, in their own eyes, they were “Hoosiers,” not bureaucrats (Hoosiers are loyal supporters of Indiana).

Still they could not overlook the fact that in Oklahoma City, a federal services building of vintage and set-aside like theirs, had been blown sky-high. When I asked why the empty slot on the directory where earlier the Director’s Office had been identified (Room 397) and when I asked why a punch-code lock on the Door to the Director’s suite, I was told they were changed when an angry veteran had threatened Rowland Christian, the Assistant Director. In an age when citizens daily watch television actors acting out their rage, these public servants know that violence can quickly come to them.

But they also know all but a few of the thousands they serve are reasonable men and women seeking only their entitlements. They are aware that the laws awarding those benefits are complex but have a confidence that their legal and technical people have appropriately categorized the conditions that establish and differentiate eligibilities. They take pride in their efforts to communicate and feel that the changes in rules and word processing in the last few years have made almost all of their letters comprehensible. They would like better form letters and even more training and work time to purge their letters of typographical errors, inconsistencies and obfuscations (For the Encyclopedia, the report was cut short at this point).

Here in this report, the case is the Reader Focused Writing Program, a bounded training system. Our study highlighted issues such as (1) the mis-match between the training and the actual work at the Regional Office and (2) the difficulties of following limits to benefits earned by veterans still living the effects of war and (3) the realization that some claims will be fraudulent claims. Pressing hard were the cold facts of eligibility, as determined by Congress, visibly displayed against the reality of difficulty, for many, of getting a loan, a hospital bed, or further education. The staff coped with issues of race and politics mixed with issues of poverty and imperfect records. The needed evidence was not easily found in physical examinations, documents and interviews, much needing repeated observation and scrutiny and further inquiry. The ability of case study to capture these human conditions came to mind again as VBA staff members and others read this report of the Indianapolis Service Center and VA services at large.

What more is illustrated there in the example? Looking at just the half report shown here, we see description of the diverse work of the staff and the activity of the training program. We recognize that several research methods were used: observation of staff at work and during training; interview of director, training officer, and workers; document review, opinion surveys, comparison of real letters written before and after training; and evaluation of training exercises. We triangulated the views of students, supervisors, and administrators as to barriers and facilitations to better letter writing. We sought a historical perspective through past reports. The four field workers met to discuss their experiences at the service centers.

The five cases were selected to provide differentiation in seniority, mix of veterans served, and ease of access. They were first treated as single case studies, but merged for treatment as a collective case study. The training activity provided a story scenario with problems to be solved and a narrative to report. In the weeks following the training it became apparent that the rate of portfolios to be processed in a day was not going to be reduced and that reader-focused writing on average would lower the productivity. The central administration may have known that all along, but they supported the training to see what would happen. The hope remained that staffing requests would be successful. They were awarded recognition in the Executive Department for a vigorous effort to do better.

Conclusion

In this chapter, we highlighted case study as an approach to inquiry, sometimes consisting of a single method, such as observation, other times a collection of methods, used to deepen our understanding of the individual case. Case study is useful in spaces of education and other social services such as health care. Other contexts, like for-profit organizations, benefit from case studies too. Everywhere where there is wonder about one or multiple cases, case study helps us understand the scene and the stories of those

involved. It acknowledges their experiences and viewpoints, it cares and empathizes, making it a humanistic endeavor. In all situations, the researcher tries to preserve the multiple realities, the differences and even contradictory views of what is happening. Of course, there are many other good approaches and ours is just one of many, stressing the particularistic, naturalistic fieldwork, keeping a sharp eye, and staying open to new impressions.

What is foxy about research is not its stealth or its sheen. It is its contribution to its field. Educational research has helped little to make education better, but when vivid, protective and valid, it makes education better understood.

Introduction

Ethnography is a systematic approach to studying everyday life a social group co-constructs through their actions and interactions over time. Ethnographers seek to answer the question “What is happening here?” from insider-driven, culturally relevant points of view. Ethnography is not a mere method for data collection or fieldwork. It is a way of seeing (Frank, 1999; Wolcott, 2008), being (Heath and Street, 2008; McCarty, 2014), languaging (Beach and Bloome, 2019), theorizing (Bloome et al., 2005; Kelly and Green, 2019a), living (Skukauskaitė, 2021) and knowing (Agar, 2006b). Ethnography is an epistemology (Green et al., 2012) and philosophy of research (Anderson-Levitt, 2006) through which ethnographers come to know and represent the complex social worlds they study. Driven by a particular kind of iterative, recursive, and abductive logic of inquiry with an emphasis on understanding different points of view (Agar, 2006b), ethnography illuminates the complex dynamic systems (Agar, 2004; Anderson-Levitt, 2006) constituting everyday life in the multilayered contexts of people’s actions and interactions with each other and with the historical, material, ecological, and non-human actors and resources.

Starting from a position of ethnography as epistemology, a way of knowing, in this chapter I briefly overview key historical foundations and challenges created as ethnography expanded and scholars developed a variety of labels and options for ethnographic work. I then explore the ethnographic space of possibilities driven by an underlying logic, followed by an explication of two kinds of ethnographic research that fit and one kind of research that may refer to ethnography but does not fit in the ethnographic space. Subsequently, I outline ethnography’s primary goals and end the chapter with considerations about ethnography’s potentials within and beyond the academic spaces.

Historical foundations and challenges in understanding of ethnography and its variations

Ethnography’s roots and contemporary quandaries

Ethnography has a long history in the social sciences and humanities and has faced numerous challenges in over a century of its use; nevertheless, it persists and is widely used in education and across disciplines as a systematic and empirical inquiry for exploring the processes and practices people culture-into-being (Skukauskaitė and Green, 2023, based on the view of culture as a verb by Street, 1993) as they act and interact with each other moment-by-moment and over time. The roots of ethnography are usually traced to anthropology and the methods of fieldwork cultural anthropologists in the late 19th-early 20th century utilized to study groups of people (“cultures”) unfamiliar to the “western” audiences. As sociologists in the early 20th century employed ethnography to study groups closer to home in modern societies, they adopted and adapted many of the anthropological fieldwork techniques and brought in social and critical theories to the study of everyday life. (For excellent exposés of ethnography’s histories, as presented from different disciplinary and theoretical frames, see, for example Atkinson et al., 2007; Beach et al., 2018b; Hackett and Hayre, 2020; McCarty and Liu, 2017, among others).

The tendency toward colonialist, Euro- and US-centered agendas of early anthropologists has been widely criticized (Beach, 2017; Bejarano et al., 2019; Hammersley, 2006; Marcus, 2008) and has led to “crises of representation” and the reflexive turn in anthropology, sociology, education and other disciplines where ethnography is widely used (Green and Bridges, 2018; Marcus, 2021). The critiques of the euro-, western-, anglo-, white-, male- and elite-centric research agendas and narrow, often faulty constructions of “culture” as a stable and geographically bounded unit (Agar, 2006a, 2019; Eisenhart, 2018), opened doors for varied perspectives and theories which have expanded ethnographic epistemology and practice (see, for example, volumes by Anderson-Levitt, 2011; Beach et al., 2018b). Contemporary ethnographies acknowledge the early roots in anthropology and

sociology (and precursors in the work of ancient historians such as Tacitus) but also question the concepts such as “culture” and “participant observation” or “insider–outsider”. Even “culture”, a concept key to ethnographic scholarship, “is a mess” (Agar, 2006a) and has no agreed-upon definition. This situation opens doors to creative and locally responsive re-conceptualizations of culture, or culture-in-the-making, as a process, a verb, a system of beliefs, patterned practices, language, and/or a combination of a variety of aspects of life of a group of people engaged in some common activity (Agar, 2019). The lack of clear definitions enhances researcher responsibility for transparency of their logics-of-inquiry and reporting, while also creating spaces for learning *from and with* the people of how the people conceptualize their own cultures, both locally situated and globally dispersed.

Variety of ethnographies

Currently, ethnography is not tied to a particular disciplinary home or national or organizational origin. It is an epistemology for inquiry into human social worlds and has been used in many countries, representing diverse languages and peoples around the globe (e.g., Anderson-Levitt and Rockwell, 2017; Milstein and Clemente, 2018; Modiba and Stewart, 2018). Ethnography is widely utilized across varied disciplines, including education, law, medicine, hospitality, marketing and many others. A variety of ethnographies are now available, and a general search can result in a plethora of adjectives for ethnography. In Table 1, I listed some of the more common labels for ethnography and classified them based on their focus.

Table 1 illuminates one potential way of classifying varied ethnographies based on their overarching focus, such as the focus on site, discipline, or phenomenon, among other possibilities. Many other kinds of ethnographies and classifications exist, and I suggest readers explore other possibilities or create their own organizational tools. In later sections of this chapter, I introduce additional classifications based on fit within an ethnographic space and disciplinary purposes in education.

What counts as ethnography?

This variety of available ethnographies dispersed across disciplines and countries makes visible the potentials of ethnography while also bringing to the fore questions of “what counts as ethnography?” or what are the parameters or characteristics of ethnography? These questions became particularly astute since the 1980s, when the adaptations of methods deriving from ethnography resulted in work that had little resemblance to the principles, practices, and logic of ethnography (Agar, 2001; Hammersley, 2006; Zaharlick and Green, 1991). One of the major influences in this dispersal of ethnography was the spreading popularity of qualitative research. While the growth of qualitative methodologies over the past five+ decades has brought positive developments and new perspectives to the study of complex social worlds, the association of ethnography with qualitative research created new challenges for ethnography (Hammersley, 2018). Ethnography has been an epistemology that enabled ethnographers to use a variety of methods (now called qualitative and quantitative) and dynamic design to explore many possible angles of overarching research questions. Ethnography was (and mainly still is) a multi-method approach (Agar, 2001; Walford, 2020) and even those from “traditional behavioral social science” (Agar, 2013) and funding organizations acknowledge it as scientific, systematic and rigorous (Shavelson and Towne, 2002).

Unfortunately, over the last few decades, the conflation of ethnography with “qualitative methods” has often led to misunderstandings and misuse of ethnography, overtime impacting its reputation and use. Without understanding the histories, theories, and epistemology of ethnography (Birdwhistell, 1977), too many researchers started calling their “qualitative” studies “ethnographic” simply because they used some fieldwork techniques or interviews, or because ethnography was viewed as a legitimate, systematic

Table 1 Kinds of ethnographies classified by focus.

<i>Classification focus</i>	<i>Kinds of ethnographies</i>
Site	organizational; urban; school; classroom; multi-sited; cyber; virtual
Discipline or field	educational; medical; ethnomethodological; linguistic; sociolinguistic
Theories or epistemology	critical; realist; cognitive; feminist; postmodern
Primary mode of inquiry	visual; sensory; video; hybrid; multimodal
Scope	focused; macro-; micro-
Phenomenon of focus	interactional; educational; performance; design; - of communication; - of ...
Relationship (or person) focus	collaborative; participatory; insider; duo ^a -, auto ^a -
Purpose	practical; applied; rapid; in/of/for education

^aDuo- and auto-ethnographies tend to be reflective accounts of an individual and may or may not study cultural groups or contribute to understanding of the patterns of activity, language, and participation in a cultural group. Auto-ethnographies which focus primarily on the author and their self-examination, personal experiences, and reflection may be closer to autobiographical or narrative accounts rather than ethnography.

research approach with which they sought to be associated. This led to “blitzkrieg ethnographies” (Rist, 1980) and a variety of studies that claim to be ethnographies but have very little to nothing ethnographic about them (Agar, 2001; Atkinson, 2015).

This spread and misuse precipitated decades of discussions and debates of what is and is not “real” ethnography. Anthropologist Michael Agar argued, the question of what is “real ethnography” is flawed since it assumes a particular definition and a predefined set of methods rather than a dynamic, adaptable logic of inquiry for studying complex social life (Agar, 2006b). Nevertheless, many have tried to define and establish parameters for ethnography, as briefly introduced in the next section. To this day, there are no clear-cut answers and no black-and-white decision points of what is “real” ethnography; nevertheless, there are a number of explicit descriptions of expectations for work that fits within the ethnographic space of acceptable ethnographies.

Attempts at defining ethnography

Agar (2006b) argued, “more than one ethnography is possible, *not all ethnographies are acceptable*” (par. 26, italics in original). What is acceptable has been presented differently by different ethnographers, groups, and publication outlets. At its most basic definition, ethnography is writing about a group of people, based on the etymology of the term derived from the Greek *ethnos*, referring to a people or culture, and *graphy*, referring to writing. Varied definitions, presentations of history, and multiple perspectives on ethnography abound in ethnography-focused journals and multidisciplinary volumes such as the *Handbook of Ethnography* (Atkinson et al., 2007), *International Encyclopedia of Anthropology* (Callan and Coleman, 2018), or *Wiley Handbook of Ethnography of Education* (Beach et al., 2018b), among others. Here, instead of reiterating the histories the readers can find in many other volumes, I present two prominent explications of ethnography and include long quotes from the original texts so the reader can follow the argument as it was constructed. The first, from the *Ethnography and Education* journal, outlines parameters for ethnography as conceptualized by journal editors who work at the intersections of sociology and education in the UK and Europe. The second is a description of ethnography offered by the American Anthropological Association in a statement for Institutional Review Boards. The commonalities between these two presentations of ethnography in two different organizations, countries, and kinds of publications lay the ground for understanding ethnography as an epistemology, with a particular kind of logic, not a mere method or set of criteria, – an argument to be developed in the subsequent section.

In the inaugural issue of the *Ethnography and Education* journal, the editors (Troman et al., 2006) outlined “the key elements of ethnographic research applied to the study of education contexts” (p. 1, bullets in the original):

- the focus on the study of cultural formation and maintenance;
- the use of multiple methods and thus the generation of rich and diverse forms of data;
- the direct involvement and long-term engagement of the researcher(s);
- the recognition that the researcher is the main research instrument;
- the high status given to the accounts of participants’ perspectives and understandings;
- the engagement in a spiral of data collection, hypothesis building and theory testing – leading to further data collection; and
- the focus on a particular case in depth but providing the basis for theoretical generalization.

These key elements emphasize the focus on culture, multiple methods, long-term engagement in the field, participant accounts, and the iterative processes of working with the data while recognizing the influence of the researcher throughout the process. These elements, drawn from a history of ethnographic research in sociology in the UK are commonly cited as parameters for work that would be considered ethnographic and publishable in the *Ethnography and Education* journal.

Anthropological perspectives on ethnography have much in common with those of sociologists, even if the emphasis on the role of theory and engagement with the people may differ in some ways (Delamont and Atkinson, 1980; Green and Bloome, 1997). The American Anthropological Association (AAA), which includes the Council for Anthropology and Education whose members have been instrumental in developing ethnographic work in education over the past century, has provided an overview of ethnography in a *Statement on Ethnography and Institutional Review Boards* (American Anthropological Association, 2004). Posing a question “What is ethnography?” the Statement explains:

Ethnography involves the researcher’s study of human behavior in the natural settings in which people live. Specifically, ethnography refers to the description of cultural systems or an aspect of culture based on fieldwork in which the investigator is immersed in the ongoing everyday activities of the designated community for the purpose of describing the social context, relationships and processes relevant to the topic under consideration. Ethnographic inquiry focuses attention on beliefs, values, rituals, customs, and behaviors of individuals interacting within socioeconomic, religious, political and geographic environments. Ethnographic analysis is inductive and builds upon the perspectives of the people studied. Ethnography emphasizes the study of persons and communities, in both international and domestic arenas, and involves short or long-term relationships between the researcher and research participants.

Multiple methods are used in ethnographic research. These include but are not limited to the following: unobtrusive direct observation, participant observation, structured and unstructured interviewing, focused discussions with individuals and community members, analysis of texts, and audio-visual records. Ethnographic methods can be employed in non-traditional ways in interdisciplinary projects that bridge the sciences and humanities.

The complexity and length of ethnographic research engenders an approach to ethics that is both dynamic and flexible. The process of obtaining informed consent may be continuous and incremental throughout the course of the research, and review of consent obtained may be periodic.

In this statement, AAA emphasizes the focus on human behavior, rituals and values in natural settings, fieldwork through immersion, focus on actions, relationships, and belief systems contextualized within multilayered environments. The Statement also emphasizes the relationality between the researcher and participants, the building of explanations from participant perspectives as well as the dynamic and flexible inquiry process, which includes the use of multiple methods to develop empirically grounded representations “of cultural systems or an aspect of culture.” The last part of the AAA definition of ethnography emphasizes the complexity of ethnographic research and the need for a continuous and flexible approach to ethics. This statement has much in common with the key elements of ethnography outlined in the *Ethnography & Education* journal. Both emphasize:

- over-time immersion in the field,
- study of cultural groups and processes,
- utilization of multiple methods,
- multiple perspectives,
- a dynamic nonlinear process of data collection and analysis,
- primacy of participant accounts, and
- ongoing relationship-building and ethics.

While many ethnographers draw on these elements to distinguish what is and is not ethnography, others have critiqued these elements as too prescriptive and/or too rigid to respond not only to the new developments in theories, technologies and ways of thinking, but also to the contemporary life with its constant movement and blurry spatial and temporal boundaries locally and globally (Agar, 2019; Beach et al., 2018a). Debates about such parameters point to ambiguities in concepts such as: culture, direct involvement, long-term, hypothesis, role of theory, and positionality of the researcher (Agar, 2006a, 2006b; Eisenhart, 2018). As one way of addressing these debates, Agar (2006b) has offered a way of looking at ethnography through the lens of its logic of inquiry rather than through the particular parameters that may or may not apply in contemporary ethnographic studies.

Ethnographic logic of inquiry

Drawing on examples of different of ethnographic studies conducted at the same site with different representations of the culture studied, Agar (2006b) explained how more than one ethnography is possible in any particular site. The ethnographies “will be different because of different combinations of ethnographer and community, different ways that a study moves, different choices and different contingencies along the way, different events in the world around the study – any or all of these can change the *trajectory* of a study over time. More than one path is possible” [par.23]. However, not every path and resulting study is acceptable as ethnography. Instead of parameters such as the ones introduced in the previous section, Agar proposed the logic of inquiry and points of view examined as ways of exploring which kinds of studies belong in an ethnographic space. He used the idea of an ethnographic space of possibilities to highlight that there are no clear binary points determining what is and is not ethnography. Instead, the logic and perspectives taken can help determine if a study is part of the space of acceptable ethnographic possibilities.

Agar (2006b) argued that the *iterative, recursive and abductive logic* and the *emphasis on the points of view different from those of an ethnographer* are key determinants of a study’s fit within an ethnographic space. The emphasis on the iterative, recursive, and abductive logic echoes the parameters for the “spiral of data collection, hypothesis building and theory testing – leading to further data collection” as presented by the *Ethnography and Education* editors (Troman et al., 2006) and *American Anthropological Association’s* (2004) call for a “dynamic and flexible” approach to ethics due to the “complexity and length” as well as the “inductive” process of an ethnographic study. The ethnographic logic refers to *iterative* processes needed for ethnographers to explore different perspectives at multiple levels of scale, *recursive* actions in building new understandings while retaining the contextual foundations, and *abductive* logic which allows the researcher to chase the rich points, develop new understandings, and fold them into the developing representations of the ways people engage in culturing processes moment-by-moment and over time (Skukauskaitė and Green, 2023). Agar (2006b, 2013) emphasizes the abductive, rather than inductive, logic of inquiry since, unlike the closed systems of inductive and deductive research processes, abduction enables multi-directional, nonlinear and dialogic explorations of:

- existing, developing, and new theories;
- differences in perspectives between the ethnographer and people studied as well as among the people;
- varied sources of data iteratively generated throughout nonlinear ethnographic processes;
- adaptable and developing methods of analyses driven by the iterative, recursive and abductive logic;
- emphasis on the point of views of the studied group’s members;
- change moment-by-moment and overtime; and
- polyvocal ethnographic representations that are culturally and contextually responsive to the group studied and accessible to the ethnographer’s audiences.

The complex dynamic processes of ethnographic inquiry also maintain the emphasis on the point of view different from that of an ethnographer (Agar, 2006b). Ethnographers do not test preexisting theories. They go into the field with the overarching question “What is going on here?” and seek to understand the often invisible processes and practices of everyday life. Ethnographers work at uncovering the taken-for-granted, mundane, invisible aspects constituting the complex social life of a group, thus making the ordinary extraordinary and the extraordinary (or unusual) ordinary and understandable.

Ethnographers take a learning stance and seek to learn something new with and from the people (Agar, 1996; Baker et al., 2023; Skukauskaitė and Green, 2023); they ask contextually grounded questions of who does and says (or cannot do/say) what, in what ways, when, where, with whom and/or what resources, for what purposes, under what circumstances, and with what outcomes and intended or unintended consequences (Green et al., 2012; Skukauskaitė and Rupšienė, 2023). In exploring these questions, the ethnographer looks for rich points (Agar, 1994), or moments that indicate differences in points of view between the insiders and the understandings of the ethnographer. Noticing these differences, surprises, and shifts in frame of reference, ethnographers chase the varied rich points utilizing the iterative, recursive and abductive logic until an explanation grounded in insider actions, language and perspectives can be constructed to demonstrate new knowledge (Green et al., 2020; Skinner, 2023).

The ethnographic logic of inquiry is iterative, recursive and abductive, and seeks new understandings arising from encounters with different perspectives. Based on Agar’s writing, the logic and point of view create the boundaries for the ethnographic space in which varied parameters and methods could be used in myriad ways to construct trajectories of an ethnographic study. One additional way of distinguishing what work belongs in the ethnographic space is to consider the study’s design and epistemological foundations.

In or out of an ethnographic space: ethnography, ethnographic studies, and use of methods derived from ethnography

Ethnographers across disciplines have long argued that ethnography is not a method but an epistemology, logic of inquiry, philosophy and a way of thinking, knowing, and living (e.g., Agar, 2001; Anderson-Levitt, 2006; Atkinson, 2017; Green et al., 2012). Using only methods, such as participant observation or artifact analysis, derived from anthropological or sociological ethnographic traditions does not make a study ethnographic, however much a scholar may want to associate themselves with ethnographic scholarship. Green and Bloome (1997) proposed a helpful distinction between two ways of engaging in ethnography that do fit within the ethnographic space and one choice for research that does not. *Doing ethnography* and *adopting an ethnographic perspective* are the kinds of studies within an ethnographic space of possibilities. However, studies that simply *use methods* derived from ethnography but do not encompass ethnographic goals and logic are not part of the space.

Doing ethnography (also called *comprehensive* or *full ethnography*) entails engaging in a study of a cultural group over time, conceptualizing culture(s) through particular theoretical and disciplinary perspectives, and conducting research through long-term participation and observation in the field. The scope of “long-term” may differ based on disciplinary parameters of the scholar and/or the studied group’s natural cycles of activity (Bloome et al., 2005; Kelly and Green, 2019b), such as, for example, a semester-long course in higher education or a year in a K-12 school. The “field” may be dispersed across physical and virtual sites (Eisenhart, 2017; Erstad and Sefton-Green, 2013), and observation, interviewing, and artifact collection may take many forms (including video, photo, and digital tools) in response to the studied group’s patterns of life (Baker et al., 2008; Bridges, 2023; Skukauskaitė and Sullivan, 2023; Tobin, 2019). In Agar’s terms, many “trajectories” are possible, but overall, a full-scale ethnography requires a study of “culture” (however conceptualized, Agar, 2006a, 2019) and broad, holistic analysis of patterns of everyday life in all its complexity and multi-layered contexts. The “whole” studied could be a whole society (as in classical ethnographies), a particular organization such as a school or business, or a particular classroom studied over time to uncover patterns of practice and insider understandings about life in their group.

Adopting an ethnographic perspective or *engaging in an ethnographic study* entails a more focused exploration of particular aspects of the group’s everyday life while still following the iterative, recursive and abductive logic, and drawing on theories of culture to conceptualize and represent the patterns of activity of the group studied. An ethnographic study, like a comprehensive ethnography, entails participating in the field over time, relationship building with the insiders (American Anthropological Association, 2004; Skukauskaitė and Sullivan, 2023), utilizing multiple methods (Agar, 2001; Walford, 2020), and chasing the rich points (Agar, 1994; Skinner, 2023) to construct understandings from insider points of view. Ethnographic studies may focus on particular activities or practices (e.g., specific literacy or mathematics events in a classroom, such as morning circle or number talks), particular places or sites (e.g., a bird identification group on a digital platform), or specific phenomena (such as gendering in science classrooms, or reflexivity in a doctoral research course). No matter the focus and scope of time, a study which adopts an ethnographic perspective and fits in the ethnographic space will draw on concepts of culture, engage in the iterative, recursive and abductive logic, and construct new knowledge responsive to insider points of view and contexts impacting the group studied.

A kind of study that does not fit into an ethnographic space is one in which the scholars merely *use methods* derived from ethnographic traditions for purposes not aligned with ethnographic logic and goals. Use of methods does not make a study ethnographic. Methods are tools for data collection and analysis and can be used in varied ways across different kinds of research designs. For example, fieldwork and observation methods, often associated with ethnography, can and have been used in studies ranging from experimental designs and process-product studies (Evertson and Green, 1986; Rex et al., 2006) to video-based qualitative studies in teacher education (Kumpulainen et al., 2012; Richards et al., 2021). Use of participant observation, conversational

interviewing, field notes, artifact analysis (among other methods used in ethnography), or a combination of methods without the underlying ethnographic logic and focus on cultural patterns of life, is outside the boundaries of the ethnographic space. Qualitative interview studies of individuals and their perspectives about something, observational studies of predetermined phenomena and variables, and multi-method or mixed method studies of populations or interventions are not ethnographic.

Doing ethnography or engaging in an ethnographic study requires understanding of the histories, theories, and epistemology of ethnography; employing the iterative, recursive and abductive logic; and seeking to construct new knowledge by examining differences in ethnographer's and participants' points of view. Ethnographers study complex patterns of practice a cultural group (not individuals by themselves) co-constructs through their discourse and actions in the flow of their everyday life, situated in multilayered contexts visible and invisible to insiders (Skukauskaitė and Girdzijauskienė, 2021). Ethnography is an epistemology, not a method. As an epistemology, it calls for theoretically grounded, consistent, and transparent logic of inquiry guided by particular ethnographic goals and ways of representing the complexities of everyday life. In the next section I introduce three kinds of possible goals of educational ethnography. While I draw on scholars in education, the distinctions they make are applicable for ways of thinking about the purposes of ethnography in other disciplines as well.

Primary goals for ethnography: ethnography *of*, *in*, and *for* education (or other disciplines)

In 1997, Green and Bloome (1997) proposed two ways of considering ethnographic spaces for those working in Education and in 2018, Bloome and colleagues (Bloome et al., 2018) expanded the arguments to Anthropology. Green and Bloome directed scholars' attention to a small word – a preposition (*of*, *in*, *for*) – whose use can help determine intended differences among goals of educational ethnographies. They argued that ethnography *of* education is typically conducted by scholars outside the discipline of education. Those scholars may use educational settings such as schools as a research site and study phenomena of interest to their particular disciplines (e.g., a psychologist studying motivation in a school setting, a kinesiologist studying physical activity of children at recess, or a sociologist studying formal and informal organizational/group structures within an educational site). Ethnography *of* education is driven by the histories, theories and goals of the scholars' home disciplines and theories outside education.

In contrast, ethnography *in* education is conducted by scholars within education. Education researchers use the knowledge, history and theories of education to explore questions of relevance to educational practice, policy, and/or theory. Ethnographers *in* education work *with* teachers, students, parents, administrators and other stakeholders to answer questions arising from engagement in the work of teaching, learning, and leading in educational settings. After all, as Ball and Forzani (2007) argued, what makes education research educational is primarily the education scholars' ability to "probe the instructional dynamic *inside* educational situations and problems" (p. 530, italics mine) and examine this complex "instructional dynamic" from multiple perspectives. Probing inside and examining educational processes and practices in context and from multiple points of view responsive to the insiders may in turn aid in informing and improving educational practice. Ethnography *in* education involves exploring these instructional dynamics and their contexts from insider questions and points of view, including perspectives and actions of teachers, students, administrators, parents, and others. While both ethnography *of* and *in* education (or any other discipline) draw on the history; cultural theories; iterative, recursive, and abductive logic; and methods stemming from ethnography's roots in anthropology and sociology, the goals, phenomena investigated, theories utilized, and involvement of and with the people will differ.

Exploring how anthropologists have studied education, Bloome and colleagues (2018) proposed a similar heuristic, adding *for* to the *of* and *in* prepositions: anthropology *of* education, *in* education, and *for* education. Writing for anthropology, Bloome et al. (2018) explained, "Anthropology of education refers to theory building in anthropology; anthropology in education refers to theory building in education; and anthropology for education refers to the enactment of educational change" (p. 2). In their encyclopedia chapter, Bloome et al. demonstrated how intersections of anthropology and education in different ways have enabled different kinds of theorizing and understanding of both anthropology and education. Here anthropology as a logic and process of inquiry is synonymous with ethnography; such use is not uncommon in the discipline of anthropology (e.g., Anderson-Levitt, 2011; Anderson-Levitt and Rockwell, 2017). Explaining anthropology (ethnography) *in*, *of*, and *for* education, Bloome et al. (2018) summarized the contributions of anthropology (ethnography) as follows (p. 7, bullets and italics mine):

- Scholarship in anthropology *of* education has deepened the understanding of how schooling and other educational processes contribute to and are influenced by socialization and cultural transmission process more generally.
- Scholarship in anthropology *in* education has built on and incorporated theoretical constructs, epistemologies, and methodologies from anthropology, reconceptualizing core education concepts and crafting a laminated theoretical framework that includes anthropological theories, the intellectual histories of educational research, other education-related disciplines, and the lived experiences of educational researchers and educators.
- Studies associated with anthropology *for* education have crafted instructional theories, models and cases that honor and build on the cultural diversity of students' communities and challenge deficit models of students from nondominant communities; they have also connected academic teaching and learning with critical social justice.

The distinctions in the goals, histories, theories, and disciplinary roots of varied ethnographies uncovered through the change of a pronoun are useful heuristics – processes of enabling discovery and learning of something nuanced that otherwise remains invisible or is taken for granted. Table 2 presents a summary of the distinctions among the underlying goals of different kinds of ethnographies within and across disciplines.

Table 2 Differentiating primary goals of ethnography within a discipline, such as education

<i>Ethnography</i>	<i>Who conducts</i>	<i>Question origins</i>	<i>Example</i>
<i>of</i>	Scholars outside the discipline	Theories from home discipline	Sociologist studying group composition and structures on a school campus
<i>in</i>	Scholars within the discipline	Problems of practice identified in collaboration with insiders	Education researcher studying how children co-construct their understanding of mathematics in an elementary classroom
<i>for</i>	Scholars within or outside the discipline, often in collaboration with community	Need for change in practice and/or theories within the discipline	A team of researchers, teachers, and community members collaborating on a community based social justice project

The heuristics of changing the pronoun when conceptualizing *ethnography of/in-/for*-a particular discipline, enable exploring the nuanced differences in the ways ethnographies are conceptualized, carried out and presented for particular audiences across fields of study. However, as [Bloome et al. \(2018\)](#) and [Green and Bloome \(1997\)](#) acknowledge, in practice, the distinctions blur as researchers collaborate and draw on knowledge and theories from across disciplines:

Social scientists *of education* often collaborate with researchers and practitioners in education and employ many kinds of knowledge generated within the disciplines *of education*; and those *in education* often employ frames, modes of inquiry and findings from disciplines within the fields of anthropology and sociology. Thus, rarely is any ethnography or ethnographic study *of education* or only *in education*. Nonetheless, the distinction is useful in examining the intellectual sites within which ethnography and ethnographic studies on education have been located (p. 186, emphasis in original).

[Green and Bloome \(1997\)](#) writing for education, [Bloome and colleagues \(2018\)](#) writing for anthropology, [Heath and Street \(2008\)](#) writing for language and literacy studies, and [McCarty \(2014\)](#) writing for educational linguistics (among many other authors writing for diverse disciplines) all highlight the need to explore disciplinary, theoretical, historical and epistemological foundations of ethnography as it is enacted in particular settings, with particular groups of people, and in particular ways. These scholars also emphasize the potentials of working across disciplines and collaborating with others to understand the educational phenomena and social life in multifaceted, layered ways.

Ultimately, despite differences, ethnographies which build on the anthropological and/or sociological roots, engage in the ethnographic logic of inquiry and seek to understand the patterned processes and practices of social life in its situated complexity over time. Ethnography focuses on “what is going on?” in a particular group moment by moment and over time, in the complex dynamic contexts shaping and being shaped by the actions and interactions of varied configurations of people within and beyond the group. I end the chapter with a summary about the kinds of questions ethnography can answer and how it has and can be used beyond publishing-focused academic spaces.

Power and potentials of ethnography

Described throughout this chapter are perspectives that demonstrate the complexity, variation, challenges and possibilities of the ethnographic epistemology within and across fields. At the core of ethnography is its iterative, recursive and abductive logic of inquiry and emphasis on understanding cultural patterns from the points of view of people creating those cultural patterns within particular groups, in specific sites and situations, through their actions and interactions moment-by-moment and over time. Anthropologist of education Kathryn Anderson-Levitt, in a chapter on Ethnography (2006) for the *Handbook of Complementary Methods in Education Research* ([Green et al., 2006](#)) provided an overview what ethnography can offer. In posing the question “what is ethnography good for?”, she explained:

It is important to understand what kinds of questions ethnography can address and what it cannot. Ethnography is useful, first, for discovering what meanings different actors are making of a situation. We cannot solve a problem or evaluate an attempted solution if we do not understand what the real problem is or how actors define it. As [Erickson and Gutiérrez \(2002\)](#) put it, “a logically and empirically prior question to ‘Did it work?’ is ‘What was the “it”?” (p. 21). Second, ethnography is useful for developing a valid understanding of local situations in all their complexity. Ethnography provides the opportunity to explore actions in their wider context and thus to describe the real-world complexity of human behavior. Third, because ethnography takes time, it gives us the opportunity to observe and understand processes as they happen. In short, ethnography is good for asking, “What is going on there?” It is a good method when we are not sure exactly what the problem is. It is good for asking, “How does this happen?” and “what does this mean?” (p. 282).

In providing the long quote here I demonstrate how an anthropologist of education who has engaged in ethnographic studies around the world, presents ethnographic potentials for uncovering complex, situated, real-world understandings of processes, practices, and discourse constituting “what is going on” and what it means for the people within the group. Ethnography’s potentials to uncover the complexity of “human behavior” and overtime processes in the wider contexts influencing and influenced by the actions of the people also invoke questions of power and who gets to conduct and participate in ethnographies.

Anderson-Levitt (2006) argued that “Because ethnography requires the researcher to understand how insiders make sense of a situation, ethnographers can draw attention to and express publicly points of view of less powerful players” (p. 283). While illuminating the lives and perspectives of the “less powerful” is an important contribution to understanding the complexities of social life in diverse social structures and cultures, she also cautions that “studying *only* the powerless can have the unintended consequence of making their behavior more visible to those in power and therefore easier to control it; it can also unwittingly collaborate in keeping the operation of power out of sight” (p. 283). Therefore, ethnographers, individually and collectively, need to study the social and cultural construction of life across varied social levels and power structures.

Considering what, whom, where, and in what ways to study, ethnographers also need to be aware of their own powers and potential influences, and thus work toward power diffusion or sharing when possible. Ethnographers start with a learner stance and position people studied as experts (Agar, 1980; Baker et al., 2023) of their lives and cultures-in-the-making (Collins and Green, 1992). Members of the group are cultural guides who choose if, when, and in what ways to help the ethnographer learn about their worlds (Skukauskaitė and Rupšienė, 2023). Listening to the people, inviting their collaboration and guidance, and partnering in the research process can diffuse some of the power differentials between an academic ethnographer and the members of the group studied (Guerrero et al., 2023; Skukauskaitė and Sullivan, 2023). Over the past few decades more work has shown the agency and power of research partners, including children, students, and teachers (e.g., Egan-Robertson and Bloome, 1998; Guerrero et al., 2023) who sometimes choose to become co-authors on research publications and presentations. But academic, publishing-focused spaces, however significant they may be to the academics, often are not the spaces of meaning or relevance to the cultural groups studied. If ethnographers involve research partners throughout the ethnographic process in transparent ways, the partners/participants construct new understandings of how ethnography can be helpful for their own purposes, be it teaching, understanding systems, learning from and with other points of view, collaborating, and/or exploring taken-for-granted aspects of daily life. The people become ethnographers of their own lives and social groups.

The power of ethnography is in its potential for the people to take it up in their own work and spaces of significance and to (re) shape their own cultural worlds by understanding how and why the systems of which they are part function. Insiders have the power to change their own practices and lives, and ethnography can be a resource (Green and Bloome, 1997) through which they develop understandings of what is happening, in what ways, when and where, in what situations, with whom, and with what intended or unintended outcomes and consequences. As Erickson and Gutteriez (2002) argued, understanding what “it” is and how “it” works in specific, real-world, contextualized lives of people acting and interacting with each other and their social and structural systems, opens doors for changing the “it”. In education, teachers, teacher educators, students, and principals have been taking up ethnography as a process of inquiry, learning, and change (Egan-Robertson and Bloome, 1998; Yeager, 2023). They demonstrate that ethnography is more than a research method – it is an epistemology, a way of knowing, and a way of living and understanding the complex changing worlds in which we live and create. Ethnography listens and honors the work and lives of people in culturally responsive, relational, situated, grounded, and transparent ways.

Introduction

The storied and situated self.

The personal and political process.

The micro and macro enmeshed.

The theoretical and theorized thickness.

Autoethnography articulates the intersection of cognitive and somatic experience. Through narrative craft, it stories a life lived, and in so doing, engages theory to make sense of how that life is socio-historically situated. It demonstrates the systemic consequences on everyday interactions, while simultaneously showing how a constellation of interactions both sustain and change those very systems. Importantly, autoethnography provides a snapshot of understanding and critique, embodying Fisher's (1984) description of *homo narrans* (p. 6), humans as narrating (and narrated) beings.

In this chapter, I first provide a broad definition of autoethnography in order to orient the reader to this method. Next, I briefly trace the history of autoethnography. I then explicate the notion of autoethnographic voice, while overviewing common instantiations of voice in autoethnographic work. I outline the evocative element of autoethnography before identifying the sort of content that autoethnographers write about. I end by providing a snapshot of where one might look to further explore autoethnography as research practice.

Autoethnography defined

Broadly speaking, autoethnography relies upon conventions of creative and performative writing (Pollock, 1998) to story personal experience while simultaneously (though perhaps implicitly) theorizing such experience. Autoethnographers believe that experience is a valid source of data. Situating such data within a variety of contexts such as historical (what historical conditions have contributed to how one understands and interprets this experience?), cultural (how do cultural assumptions and affiliations impact one's understanding and interpretation of this experience?), and political (how do power imbalances inform how one understands and interprets this experience?), highlights the relationship between the personal and the cultural. At the same time, autoethnographers understand that these elements (e.g., personal, historical, cultural, political, economic, sociological, and so on) can never be so easily compartmentalized. In short, autoethnography is a way of theorizing the world at large through the lens of the personal. Theory helps us explain; story helps us personalize theory.

Autoethnographers often make use of conventions of creative writing in their scholarship. First-person voice is a common element, though purposeful use of second and third voice can have a powerful impact [see, for example, Pelias (2000), for a compelling use of second person]. Dialogue may make its way into an autoethnographic essay [see, for example, Pensoneau-Conway and Valenta (2021) for how they use dialogue to show their relationship development]. Variation in the use of font, spacing, boldface and italics, and other typesetting options brings nuance to an autoethnography, and invites the reader to reflect upon not just the overall message of a piece, but also what particular differences may symbolize about the intention of the author, and for the interpretation the reader makes.

For example, Gingrich-Philbrook's (2015) chapter opens in third person: "One hears a lot about home" (p. 199), which serves (to this reader) as a broad opening, allowing any reader to place themselves in the subject position of "one." The second sentence shifts into first-person plural and third-person plural: "If we have to go there, for example, they have to take us in" (p. 199). The use of first-person plural creates a sense of belonging for those who may identify with the "we," along with a sense of separation between "we" and "they." While reference to "me" is made in the first paragraph, Gingrich-Philbrook gives a greater sense that this is a personal essay in the first sentence of the second paragraph: "Working on this essay, I learned I am the very last person

a reader should trust to articulate what home does or does not comprise or afford—at least that ‘home’ normative forms of family and patriarchy want us to think of when we hear that word” (p. 199–200). Here, Gingrich-Philbrook further strengthens the connection between himself and the reader (“I” and “we”) while also invoking cultural manifestations of patriarchy and the construct of *family*. This example demonstrates the care and consideration autoethnographers take with each word, as it stands alone and as it exists in relation to other words, all in the service of forwarding a particular theme or message, while still remaining open for the reader to interpret the text in their own particular way, as well.

Autoethnography: an historical view

Autoethnography’s origins are somewhat contested. The term itself—“auto” + “ethno” + “graphy,” or, the self writing about culture—has roots in ethnographic research practice. David Hayano (1979) is credited with bringing autoethnography into effectual visibility in the field of anthropology, a fitting location given anthropology’s focus on culture. Hayano identifies his first encounter with the term as being in a 1966 structuralism seminar. In that setting, the lecturer, Sir Raymond Firth, used *autoethnography* to refer to an element of Jomo Kenyatta’s 1938 study of his own Kikuyu people. The 1938 occurrence referenced the “question of judging the validity of anthropological data by assessing the characteristics, interests, and origin of the person who did the fieldwork” (p. 100). In this sense, autoethnography referred to the anthropologist’s concern with how an ethnographer writes ethnographically about one’s “own people” (p. 99). Yet, in Hayano’s explication of autoethnography, there is still the prominent element of a group, of which the ethnographer is but a part. The ethnographer recognizes themselves as a member of the group, yet the group still remains the focus. The self comes as a result of the group, rather than starting with the self.

Others credit literary and feminist scholar Françoise Lionnet (1989) with using *autoethnography* in a way that’s more in line with autoethnography of the past 30 years. Lionnet used the term to describe the 1942 autobiography of writer and anthropologist Zora Neale Hurston, *Dust Tracks on a Road*. Lionnet writes, “what I would like to suggest here is that *Dust Tracks* amounts to autoethnography, that is, the defining of one’s subjective ethnicity as mediated through language, history, and ethnographical analysis; in short, that the book amounts to a kind of ‘figural anthropology’ of the self” (p. 99). In this way, the self provides an account of their subjective location within a group, rather than foregrounds the group that happens to be comprised of selves. This situated self—different from a group/culture of selves—is the focus of autoethnography as it is most commonly manifested today.

And yet, the elements of self and other, self and group, self and culture cannot be so easily disconnected. Indeed, autoethnography aims to illuminate culture through the narration of experience, and is “an evocatively rendered, aesthetically compelling, and revelatory encounter” (Adams and Holman Jones, 2008, p. 375). It is famously described by autoethnographic pioneer Carolyn Ellis (2004) as a “back and forth”:

Back and forth autoethnographers gaze: First they look through an ethnographic wide angle lens, focusing outward on social and cultural aspects of their personal experience; then, they look inward, exposing a vulnerable self that is moved by and may move through, refract, and resist cultural interpretations. As they zoom backward and forward, inward and outward, distinctions between the personal and cultural become blurred, sometimes beyond distinct recognition. (pp. 37–38)

And it is this back and forth that distinguishes autoethnography from autobiography.

Autoethnography and voice

The autoethnographer’s voice functions as the mechanism by which the back and forth happens, by which culture is communicated. The *what* of the voice becomes important, and sets autoethnography apart from other life writings. In other words, the “ethno” serves as a key marker of autoethnography. The crisis of representation is but one condition that has created the possibility for autoethnography. Pensoneau-Conway and Toyosaki (2011) explain that autoethnography (along with more critical ethnographic work) responds to the crisis of representation, in which scholars are no longer able to ignore the politics of representation (of the self and the other), the interdisciplinarity of scholarship, and the colonizing history of scholarly practices (relevant to this discussion, of ethnography in particular). They trace the development of autoethnography in this light, acknowledging the growing skepticism of the ethics of more traditional ethnographic practices and a healthy questioning of the influences of the researcher on all aspects of the research process. Autoethnography provides one response to the concern regarding the relationship between self and other, by positioning the self *as* other. Thus, the autoethnographic voice provides rich insight into the makings of experience, and autoethnographers understand *voice* to be noun and verb.

Both singular and plural, autoethnography voices experience from multiple perspectives. In solo-authored work, readers may encounter the author writing from a seemingly singular voice, as in Duff’s (2021) narratives surrounding the COVID-19 pandemic, Adams’s (2011) exploration of the closet, or LeMaster’s (2013) evocative work living on/in the border of gender, race, and family. Or, readers will meet the multiple selves of that author, who writes as a multi-voiced individual, as in Carol Rambo’s (1995, 1996) work, known for the usage of the “layered account.”

The “auto” in autoethnography often points to a singular self and/or singular author. The question of authorship raises interesting considerations for autoethnography, and for autoethnographers. Postmodernism inspires some of these questions, including:

- Who owns a story?
- Does a story necessarily have more than one author, since no experience can be entirely isolated from other actors/authors?
- Does the *auto* in autoethnography preclude the question of multi-authorship?
- Does a fractured sense of self—that the self can never be contained into one coherent subject—mean that all stories are necessarily multi-authored?

There are many ways to answer these questions. Some scholars have developed methods resonant with autoethnography, but that address the question of solo-authorship. For example, [Alexander et al. \(2012\)](#) use “tri-autoethnography” to bring their three voices together in a beautifully told exploration of family relationship patterns. [Gale et al. \(2012\)](#) poetically and dialogically paint the collaborative writing process. [Toyosaki et al. \(2009\)](#) developed community autoethnography as an engagement in “dialogical theorization” of whiteness, in order to honor the relational aspect of experience. Similarly, [Chang et al. \(2013\)](#) offer an in-depth methodological primer on collaborative autoethnography, though not to diffuse the specificity of autoethnography. Rather than understanding autoethnography as only a solo practice (a focus on the “auto,”), these collaborators acknowledge the contribution of the “ethno” (culture/group) to the “auto.” It’s quite common to find autoethnographers blending their stories with those of others, as [Boylorn \(2013\)](#) did in *Sweetwater: Black women and narratives of resilience*. These works answer the call put forth by [Ede and Lunsford \(2001\)](#) to “enact contemporary critiques of the author and of the autonomous individual through a greater interest in and adoption of collaborative writing practices” (pp. 355–356). In some of these examples, authors use autoethnography as part of a multi-method approach to their work. In other cases (such as with Alexander, Moreira, and Kumar; and Toyosaki, Pensoneau-Conway, Wendt, and Leathers), the authors claim that their work still constitutes autoethnography, but in such a way that highlights the intersubjective nature of selfhood.¹

Additionally, autoethnographic voice manifests in a variety of forms. Though much scholarship is found in a more traditional written format, even on the page, autoethnography can look very different from one to the next. [Spry \(2011\)](#) plays with space and place in her poetic autoethnography, as does [Cosenza’s \(2013\)](#) autoethnographic performance of queer futurity. Cosenza’s piece also demonstrates the literal embodiment of autoethnography, in its mediated form. On the surface, this seems contradictory to my earlier gesture toward “graphy” as “writing.” However, embodied/performed autoethnography works against the scriptocentrism that critical scholars, especially in the humanities [e.g. [Conquergood \(2002\)](#)], have argued against. “More often than not, subordinate people experience texts and the bureaucracy of literacy as instruments of control and displacement” ([Conquergood, 2002](#), p. 147). Indeed, Cosenza specifically puts her autoethnography on its feet as a form of resistance to the ways text had been used against her as a dyslexic scholar. These scholars, and others, co-opt the written form, in a sense, to allow access to different forms of autoethnography.

Regardless of the shape of autoethnography, such work asks readers/audience members to sit with questions of voice and authorship. It comes to a question of who has the authority to narrate experience, and thus, narrate culture. Whose story is it? Is it the story of the self? And in a poststructuralist turn, is there a “self” who can speak in the first place ([Nelson, 1985](#))? Rather than pose an answer to these questions, the autoethnographic enterprise plays with and explores these questions as part of its practice.

Evocative autoethnography

Autoethnographic writing is highly evocative and personal. While some may advocate for a more analytical and distanced narrative ([Anderson, 2006](#)), others would argue that these two (evocative writing and analysis) are not mutually exclusive. Indeed, autoethnography “hinges on the push and pull between and among analysis and evocation, personal experience and larger social, cultural, and political concerns” ([Adams and Holman Jones, 2008](#), p. 374). As [Berry \(2006\)](#) explains, through telling an evocative story autoethnographically, a scholar creates a communicative interaction with a reader, an interaction that can speak loudly about (and thus, analyze) a social phenomenon. Further, not only does embodied, lived experience constitute valid data for analyzing cultural phenomena, but for many autoethnographers, the writing process itself is the act of inquiry. That is, rather than being a *representation* of data collection and analysis (as it might be for more conventionally ethnographic approaches), autoethnographers understand the writing/crafting process as illuminating cultural patterns and systems that impact how we see ourselves and others ([Pollock, 1998](#); [Richardson and St. Pierre, 2005](#)). These insights often come within the act of writing, rather than the writing only being the representation of these insights.

¹While it is beyond the scope of this chapter to reference all instantiations of autoethnography and approaches that may not be autoethnography proper, but rather, autoethnography adjacent or may use elements of autoethnography, I appreciate a reviewer’s point that such a broad approach to what may be considered autoethnography risks giving up the specificity of the method.

The what of autoethnography

Autoethnographic narrative seeks to articulate how the body moves through the world, in all of its shifting identifications and manifestations. Through story, the autoethnographer narrates the process of how identity is constituted in and through the body. As [Gannon \(2006\)](#) explains, “The authority for the story begins with the body and memories of the autoethnographic writer at the scene of lived experience” (p. 475). And in autoethnographic scholarship, that experience runs the gamut from the constitution of a gay male body’s becoming ([Berry, 2007](#)); the transformative experience of recognizing and owning White privilege ([Boyd, 2008](#)); the tricky, painful, and necessary experience of gender transition and family dynamics ([Dent, 2002](#)); the grief process ([Ellis, 2009](#)); narrative reframing of abuse ([Kiesinger, 2002](#)); disability and qualitative research ([Polczyk, 2012](#)); and mental health ([Collins, 2017](#); [Iago, 2002](#)).

Specific to the field of education, autoethnographers have taken up a number of topics, ranging from the academic as tourist ([Pelias, 2003](#)); the relational intricacies of a teaching and advising relationship ([Pensoneau-Conway and Valenta, 2021](#)); identity politics in higher education ([Toyosaki, 2007](#)); self-disclosure, sexual orientation, and the classroom ([Gust, 2007](#)); professional life of teacher educators ([Hayler, 2011](#)); disability and educational contexts ([Smith, 2013](#)); and professional development of and barriers faced by leaders of color in academia ([Chang et al., 2014](#)). Still, autoethnography remains underexplored and underutilized in K-12 education in the US.

Outlets for autoethnographic scholarship

Interested scholars have quite a number of outlets for finding and publishing autoethnographic work. These include *Journal of Contemporary Ethnography* (Sage), *Journal of Autoethnography* (University of California Press), *Qualitative Inquiry* (Sage), and *Cultural Studies* ← → *Critical Methodologies* (Sage). *Liminalities: A Journal of Performance Studies* (Creative Commons) regularly publishes mediated autoethnographies. In addition, the International Association for Autoethnography and Narrative Inquiry (IAANI, n.d.) hosts an annual Symposium on Autoethnography and Narrative (formerly the Doing Autoethnography conference). Likewise, the *Critical Autoethnography* (n.d.) group also hosts a regular conference. The International Congress of Qualitative Inquiry is very welcoming toward autoethnographic work, and includes an autoethnography “Special Interest Group.” Finally, books such as *Doing Autoethnography* ([Pensoneau-Conway et al., 2017](#)), *Sage Handbook of Qualitative Methods* ([Denzin and Lincoln, 2017](#); this *Handbook* has been publishing chapters related to autoethnography at least since the second edition in 2000) and *Handbook of Autoethnography* ([Adams et al., 2022](#); [Holman Jones et al., 2013](#)) have all given visibility and legitimacy to autoethnography as research method.

Autoethnographic futures

In more recent years, scholars have begun to ask hard questions of autoethnography, questions that aim to bring into relief the multitude of marginalized voices and experiences. In calling for autoethnography as a praxis of social justice, [Toyosaki and Pensoneau-Conway \(2013\)](#) argue that “while social justice may be fundamentally *social* [and autoethnography may seem to be fundamentally *individual*], our argument for autoethnography as the praxis of social justice entails an examination of the self who engages in social justice/responds to social injustice” (p. 560). Autoethnography is beginning to heed the call for a more critical perspective, one that can respond to the current cultural, global, digital, and political moment. Such works include *Critical Autoethnography: Intersecting Cultural Identities in Everyday Life* ([Boylorn and Orbe, 2021](#)), along with [Atay’s \(2020\)](#) attention to mediated autoethnography and transnational and postcolonial autoethnographies ([Atay, 2018](#)), and [Parks’s \(2021\)](#) intersectional autoethnography of race and disability.

While autoethnography is enjoying relative acceptance in academia, questions remain about the existence of a self, the role of the self in the construction of the other (and vice versa), and the limits of scholarly practice. While no method alone can (or should) claim to be able to respond adequately to any of these questions, autoethnography finds hope in the stories that work toward some semblance of resolution. Embracing the ontology of *homo narrans* may provide a humanizing perspective to a scholarly orientation toward understanding social phenomenon. The generative component to storytelling may just be a key to seeing one another more fully, more humanely, and more justly.

Glossary

Abduction A form of reasoning where the researcher considers various explanations for observed data and then tests these explanations against the data to ultimately yield the most plausible explanation of the observed phenomenon (See Babchuk, 1997; Bryant and Charmaz, 2007a,b; Guetterman et al., 2019; Guetterman et al., in preparation)

Axial coding Strauss' (1987) and Strauss and Corbin's (1990) term for the delineation of hypothetical relationships between a category and its subcategories, and between the category and other categories through use of the coding paradigm (i.e., conditions, context, action/interactional strategies, and consequences)

Category A set of codes that share common properties. Categorizing is the process of abstracting these codes into an analytic concept or pattern

Coding The data analysis process of applying descriptive labels to data or data sets for analytic purposes to organize data at increasingly higher levels moving from codes to categories, concepts, or themes to theory. Grounded theorists advocate different forms of coding from open, initial, axial, and substantive coding to increasingly selective, focused, or theoretical techniques used to develop the emerging theory

Conditional/consequential matrix A heuristic tool diagramming the relationships between macro and micro conditions and consequences

Constant comparative/-ison An analytical ongoing and iterative process central to the grounded theory methodology widely incorporated by other qualitative approaches in which the researcher continually compares emerging data in increasingly abstract levels to develop concepts, categories, and theory

Ethnographic grounded theory A hybrid qualitative research approach that systematically combines elements of ethnography and grounded theory

Grounded theory An overarching term denoting a specific research design geared at developing a midrange theory, explanation, typology or conceptual framework grounded in the data as well as the end product of this form of research

Maximum variation First identified as a concept by Glaser and Strauss (1967), this is the principle of purposefully sampling data from people or cases exhibiting widely varying circumstances in order to cast as wide a net as possible to study the general characteristics of a phenomenon before narrowing, via **theoretical sampling**, to characteristics befitting the model in development

Memoing or memo-writing A key part of the grounded theory process leading toward theory-generation; a memo can be reflective, theoretical, procedural, interpretive, or linked to a code or category; memo-writing happens in iterative cycles together with data collection and coding

Middle-range theory (c.f., grand or “formal” theories) A primary aim in most grounded theory studies capturing “abstract renderings of specific social phenomena” (Charmaz, 2014, p. 9); contrasts with contrast to so-called “grand” theories such as Marxism or feminist theory; Charmaz (2014) adds other grounded theory aims such as substantive theorizing, extending extant theory with new concepts, and challenging extant theory (pp. 248–259)

Open coding The initial coding process in grounded theory which involves the breaking down, analysis, comparison, and categorization of data (Strauss and Corbin, 1990, p. 61). In constructivist applications this stage is referred to as *initial* coding (Charmaz, 2014) but is much the same process

Selective coding The process by which categories are related to the core category, and these relationships are validated against the data. In systematic or Straussian grounded theory, this becomes the basis for the grounded theory

Theory A substantive or formal explanation or model of the social psychological phenomenon being studied that emerges from data analysis throughout the research process

Theoretical sampling A unique form of purposive sampling that involves the ongoing selection of sites, participants, and events that are strategically selected to assist the development of theoretical categories and concepts to enrich the emerging theory

Theoretical saturation (sufficiency) A condition of a grounded theory study when newly collected data do not yield additional insights to the further development of the relationships between categories and development of the emerging theory signaling the end of the data collection process

Theoretical sensitivity The ability of the researcher, through the specific grounded theory analytic procedures chosen, to recognize the theoretical direction(s) and relevant data and reflect upon it with the help of theoretical terms or concepts

Introduction

Grounded theory is an inductive—or perhaps more accurately—an abductive method aimed at generating theory from empirical data collected in the field. Often viewed as both a process and product of social research, grounded theory has been argued to be the most utilized contemporary qualitative research methodology (Babchuk, 1997; Bryant and Charmaz, 2007a; Guetterman et al., 2019) but is not limited solely to the collection and analysis of qualitative data having been employed in both quantitative and mixed methods research (Glaser, 2008; Glaser and Strauss, 1967; Holton and Walsh, 2017; Johnson et al., 2010; Johnson and Walsh, 2019; Walsh, 2014, 2015). Due in part to its positivist/post-positivist epistemological origins and the systematic and rigorous foundational aspects advanced by its co-founders, it can be considered a particularly appealing “transition methodology” for quantitatively trained scholars interested in adopting qualitative methodologies for their research or incorporating it in mixed methods designs (Guetterman et al., 2019; Howell Smith et al., 2020; Johnson and Walsh, 2019; Johnson et al., 2010). Although its applications in real world settings can prove challenging to both novice and more experienced researchers faced with a wide array of conflicting interpretations as to how best to utilize this methodology, taken together the various iterations of this methodology have proven to be particularly successful over time and across disciplines for advancing social research (Charmaz, 2014; Charmaz and Bryant, 2010).

Overview of article

This article begins with an overview of the origins and history of grounded theory followed by a discussion of grounded theory’s extended family of approaches that have been widely adopted by contemporary researchers. We then focus on conducting grounded theory research in education by considering shared core attributes of this methodology, procedures for conducting grounded theory research, criteria for evaluating grounded theory studies, and suggestions for getting started in grounded theory research. We conclude this article through a discussion of future directions where we consider other potentially fruitful applications of grounded theory including **ethnographic grounded theory**,¹ mixed methods-grounded theory, and designs that leverage grounded theory in

¹Bold-face terms are defined in the Glossary section.

service of critical race theory and social justice aims. It is our intent to provide a comprehensive yet succinct overview of grounded theory in order to introduce readers to this popular approach and to point those new to this methodology in the right direction as they consider taking on this form of inquiry.

Origins and history of grounded theory

In 1960, the University of California-San Francisco (UCSF) School of Nursing hired Anselm Strauss to teach medical sociology and serve as inaugural Director of the School's newly minted Department of Social and Behavioral Sciences (Birks and Mills, 2015). He helped establish the first graduate program in nursing in the US to guide nurses in their Ph.D. research, a position he held until his retirement in 1987 (Babchuk, 2011). Strauss was a byproduct of the iconic Chicago School of sociology where his training was strongly permeated by an emphasis on naturalistic (ethnographic) fieldwork, symbolic interactionism, and pragmatism via the influences of Pierce, Dewey, Mead, Park, and Blumer (Bryant, 2017; Hadley, 2017; Olson, 2018). To help in these tasks and in conducting research as part of a 4-year grant on death and dying, Strauss enlisted the aid of Barney Glaser, who was fresh off his doctoral work at the prestigious Department of Sociology at Columbia University, where scholars such as Paul Lazarsfeld and Robert Merton were advancing quantitative research methodologies and pioneering "theories of the middle range" (Babchuk, 2011, emphasis added).

Accompanied by Jeanne Quint Benoliel, then a doctoral student in nursing—who seems to have played an important yet largely uncredited role in the methodology's development, analogous to that of Rosalind Franklin in the discovery of DNA—Glaser and Strauss conducted collaborative research on death and dying in hospitals in order to forge a new approach to social research they labeled grounded theory. This methodology was explicitly designed to systematically generate theory from empirical data collected in the field (Babchuk, 2011; Bryant, 2017, 2019). Formally introduced in *The Discovery of Grounded Theory: Strategies for Qualitative Research* (1967), the methodology [that] Glaser and Strauss sought to develop had to be "useful for both verification and generation of theory" through employing quantitative and qualitative data with a particular emphasis on qualitative research "because the crucial elements of sociological theory are often found best within a qualitative method" (p. 18). In *The Discovery of Grounded Theory*, they sought to advance a systematic qualitative approach equivalent to the predominant quantitative methodologies of the era outlining fundamental principles of grounded theory including the constant comparative method, **theoretical sampling** and **saturation**, simultaneous data collection and analysis, and **memo writing** (Glaser and Strauss, 1967; Guetterman et al., 2019; and see Glaser, 1965).

Unfortunately, *The Discovery of Grounded Theory* (1967), together with their two other prominent early texts, *Awareness of Dying* (1965) and *Time for Dying* (1968), provided little guidance on how to employ these fundamental principles to successfully conduct grounded theory research (Bryant, 2017). Unbeknownst to Glaser and Strauss, or anyone at this time, underlying this collaboration and the publication of the "death and dying trilogy" were fundamental differences in how these two scholars envisioned the use of this methodology to advance social research. They taught and worked together for almost 10 years before Glaser—after being denied tenure at UCSF—left to conduct his own research and establish his own publishing company he titled Sociology Press in Mill Valley, California in 1970.

Diverging interpretations

Glaser and Strauss parted ways. Their grounded theory "divorce" was of a magnitude rarely seen in academe, and one which has been well documented in the grounded theory literature as well as being the subject of the first author's doctoral dissertation research (Babchuk, 1996, 1997, 2008, 2011; Birks and Mills, 2015; Guetterman et al., 2019; Heath and Cowley, 2004; Kelle, 2007). As will be discussed in more detail in the next section, both Glaser and Strauss went on to promote their own versions of grounded theory that shared elements of the original design but differed substantially on key attributes particularly relating to the challenging process of data analysis. Others would ultimately offer their own epistemological and operationally repositioned versions to constitute grounded theory's "family of methods" a term first coined by Anthony Bryant (Babchuk, 2011; Bryant, 2017, 2019; Bryant and Charmaz, 2007a), "family of variants" (Bryant, 2019), "compendium of methods" (Corbin, 2009), "constellation of methods" (Charmaz, 2014), or "package of methods" (Birks and Mills, 2015). Although several scholars advocate for three major grounded theory approaches including (1) Classic, Emergent or Traditional (Glaserian) Grounded Theory, (2) Systematic (Straussian) Grounded Theory, and (3) Constructivist (Charmazian) Grounded Theory (Bryant, 2017, 2019; Creswell and Poth, 2018) we include Adele Clarke's (4) Postmodern/Situational as a fourth variant (Babchuk, 2011; and see Reichertz, 2007, who discussed five variants). Other sub-approaches of this methodology that deserve consideration are Dimensional Analysis (Bowers and Schatzman, 2009) and Hadley's (2017, 2019) Critical Grounded Theory. Although each approach advances its own unique recommendations for conducting grounded theory research, most incorporate several core features of grounded theory as originally envisioned by the co-founders (Charmaz, 2014; Guetterman et al., 2019).

As stated in the introduction to this article, grounded theory is often considered the mostly widely utilized contemporary qualitative research methodology, although systematic reviews of the grounded theory literature (Babchuk, 1997; Charmaz, 2014; Guetterman et al., 2019) have indicated that many studies purporting to be grounded theory analyses should perhaps not be accorded the grounded theory label as will be discussed in more detail later in this article. Regardless, the historical significance of grounded theory methodology cannot be understated, as Merriam and Tisdell (2016) have argued that *The Discovery of Grounded Theory* (1967)

represents one of the two most influential works in the history of the qualitative tradition (Babchuk, 2011), and Charmaz (2000) proclaimed that this work “served at the front of the qualitative revolution” (p. 509) that began in the 1960s. Similarly, Denzin and Lincoln’s (2005) “Second Movement of Qualitative Research” or the “Modernist Phase”—also referred to by them as the “golden age of rigorous qualitative research”—was “bracketed in sociology by *Boys on White* (Becker et al., 1961) at one end and the *Discovery of Grounded Theory* (Glaser and Strauss, 1967) at the other” (p. 17, and see Babchuk, 2011; Birks and Mills, 2015).

Grounded theory’s contested family of approaches

The early collaborative works of Glaser and Strauss (1965, 1967, 1968, 1971) provided little guidance to the aspiring grounded theorist on how to design and conduct this form of research. To make explicit grounded theory’s fundamental procedures outlined in the *Discovery of Grounded Theory* (1967) and to better train doctoral students in the use of this methodology, Anselm Strauss alone (1987) and with former UCSF doctoral student Juliet Corbin (1990, 1994, 1998) advanced their own highly structured and systematic guidelines. Influenced by Glaser’s classic text *Theoretical Sensitivity* (1978) and his notions of theoretical coding and coding families, Strauss—and later Strauss and Corbin—put more emphasis on theory verification rather than theory generation and they employed open, axial, and selective coding procedures (Charmaz, 2014; Kelle, 2019; Strauss and Corbin, 1990). Central to this approach is the axial coding process that is a procedure that further extends the initial open coding phase by systematically exploring the relationships between categories and sub-categories through the use of a coding paradigm specifying causal conditions, contextual and intervening conditions, and consequences (Babchuk, 2008; Creswell and Guetterman, 2019; Strauss and Corbin, 1990). This process sets the stage for selective coding and the identification of a core category of the studied phenomenon integrating the categories and leading to the generation of theory. Introduced in 1990 and later elaborated in the second edition (1998) of their text, Strauss and Corbin also introduced their conditional (later labeled conditional/consequential) matrix, a heuristic tool diagramming the relationships between macro and micro conditions and consequences (Strauss and Corbin, 1990, 1998). An example of Systematic or Straussian Grounded Theory is Lovell’s (2016) study geared at explaining parental involvement in childhood health and nutrition of low-income Early Head Start families.

Strauss and Corbin’s texts were generally well received as they represented the first attempts to provide systematic guidelines as to how to conduct grounded theory analysis, and they were further endorsed by Creswell in multiple editions of his widely read *Qualitative Research Inquiry and Research Design: Choosing among Five Approaches* texts (see Creswell and Poth, 2018). Firmly believing that Strauss and Corbin’s (1990) interpretation of the grounded theory methodology deviated too greatly from the tenets laid out in *The Discovery of Grounded Theory* (1967), Glaser labeled their approach “full conceptual description” and in response, after Strauss and Corbin ignored his requests for them to pull the text, he published his own corrective text through his publishing house Sociology Press—*Basics of Grounded Theory Analysis* (1992)—he claimed could be used to set “the average researcher back on the correct track to generating a grounded theory” (p. 6). Glaser forcefully argued that Strauss and Corbin’s coding procedures and paradigm were too prescriptive and structured, and that these represented a type of approach he and Strauss had originally attempted to distance themselves from in their 1960s work recommending procedures that were forced rather than emergent. Systematic Grounded Theory has historically been adopted for use by graduate students and less experienced researchers who can use the relatively straightforward set of procedures as outlined by Strauss and Corbin, but this formulaic approach may be potentially too constrictive for some and seems to have declined in popularity in recent years.

In contrast, Glaser’s advanced a version of grounded theory he believed to represent a seamless development from *The Discovery of Grounded Theory*, extending to *Theoretical Sensitivity* (1978), to a series of his more contemporary works published through Sociology Press. In *Theoretical Sensitivity*, Glaser outlines his theoretical coding model which helps the analyst to further structure emerging categories by drawing upon 18 theoretical coding families (further expanded and modified in 1998). Theoretical codes act to conceptualize how the initial substantive codes developed during open coding relate to each other as hypotheses to be integrated in the emerging theory (Charmaz, 2014; Glaser, 1978; Kelle, 2007). Theoretical sensitivity—the ability for the analyst to recognize and reflect upon relevant empirical data during analysis—is key to successfully utilizing the methodology. In his version, Glaser places more emphasis on theory generation than theory verification through constant comparison, open, selective, and theoretical coding, and much inductive thinking (Hadley, 2017). Perceived by some as too dense and formidable for many researchers to tackle, Glaserian Grounded Theory has gained considerable prevalence in recent years thanks in part to the influence of contemporary scholars such as Martin and Gynnild (2011) and Holton and Walsh (2017) who demonstrated the potential of this approach. An example of Classic or Glaserian Grounded Theory is Giske and Artinian’s (2007, 2008) study of coping by patients in a gastroenterology ward (and see Bryant, 2019, for further discussion of this study).

Glaser and Strauss are considered the first generation of grounded theorists and the founders of this methodology. However, a second generation represented primarily by some of their former students at UCSF including Juliet Corbin, Kathy Charmaz, Adele Clarke, Phyllis Noerager Stern, and others (Stern and Porr, 2011) have reshaped the grounded theory landscape. The work of Charmaz (2000, 2006, 2014) and Clarke (2005, 2009, 2019) in particular, has been seen by many as more aligned with epistemological, theoretical, and methodological advancements taking place in the social and behavioral sciences over the past few decades (Babchuk, 2008; Bryant, 2002, 2017, 2019; Bryant and Charmaz, 2007b; Charmaz, 2014).

Rejecting objectivist, positivist/post-positivist assumptions she believed were at the epistemological core of both the Glaserian and Straussian approaches, Charmaz developed her own constructivist brand of grounded theory (2000, 2006, 2007, 2014) and was later joined by Antony Bryant who helped champion and extend her approach (Bryant, 2017, 2019; Bryant and Charmaz,

2007a,b, 2019). This approach sidesteps the pure inductivism of Glaserian Grounded Theory and the rigid formulaic procedural guidelines of Straussian Grounded Theory. Instead, it advances a more democratic approach aimed at co-constructing rather than discovering or verifying grounded theories through shared interactions between researchers and multiple social actors (Charmaz, 2014). Charmaz also rejects Glaser's viewpoint that grounded theory should evoke one core category or process. She embraces the notions of multiple ways of knowing (following Strauss), a focus on basic social processes, and rejects a heavy reliance on dogmatic methodological adherence to produce theory (Charmaz, 2014; Hadley, 2017). She also incorporates open coding techniques she refers to as *initial* coding, followed by a secondary focused coding stage that collapses codes into similar categories, and then theoretical coding to further develop the emerging theory. Charmaz is a strong advocate of using gerunds (typically words ending in “-ing” in English that are verbs acting as nouns) in coding (as recommended by Glaser (1978)) and relies upon the core processes of constant comparison, theoretical sampling, and memoing in conducting grounded theory research. In her version of grounded theory, the researcher acknowledges her or his key role in the research itself and at the same time elevates the participant to more equal standing in the co-construction of mutual derived explanations of the studied social phenomenon. Unlike previous approaches, Charmaz maintained that the data do not speak for themselves and instead rest on the interactions of researchers and participants (Olson, 2018). An example of Constructivist or Charmazian Grounded Theory is Lynch-O'Brien et al. (2021) who developed a substantive theory of “transference” to explain “the social process by which educational and attitudinal impacts intended by program leaders for program participants are filtered by citizen scientists and transferred to others” (p. 1) in a citizen science program.

Also rejecting the objectivist approaches of grounded theory's co-founders, Adele Clarke promotes her own well-conceptualized version of postmodern/situational grounded theory she labeled Situational Analysis. Drawing from Chicago School symbolic interactionism, the Straussian notion of social world/arenas theory, the post-structural theorizing of Michel Foucault and other post-modern scholars, and assumptions driving constructivist grounded theory, Clarke's Situational Analysis (Clarke, 2005, 2019; Clarke and Friese, 2007; Clarke et al., 2016) employs the use of cartographic mapping techniques and the making of situational, world/arenas, and positional maps to best illuminate social situations of power and oppression viewed holistically from multiple overlapping lenses. Clarke also rejects oversimplified Glaserian and Straussian notions of a single social process, “focusing instead on analyzing relationalities both within and across three kinds of maps” (Clarke, 2019, p. 16). In other words, Clarke is more focused on the social situation than on the analysis of basic social processes. An instance of this approach comes from the work of Pérez and Cannella (2013) who “provide examples of situational mapping from a study focusing on disaster capitalism and the privatization of the public education system in post-Katrina New Orleans” (p. 505).

In addition to varying epistemological, theoretical, and methodological interpretations relating to the design and conduct of grounded theory research outlined above, there have been numerous other controversies underpinning this approach over the past fifty years. These include the nature of the research process—inductive, deductive, and abductive—the timing of how relevant literature should be incorporated in grounded theory research, conflicting interpretations of meaning and applications of the terms “data” and “theory,” use of theoretical sampling and sample size, theoretical saturation, positionality of the researcher, what constitutes a grounded theory study and what the findings should look like (e.g., theory, typology, model, etc.), and evaluative criteria on how to assess the integrity and contribution of a grounded theory study (Babchuk, 1997, 2008; Bryant, 2002, 2017; Bryant and Charmaz, 2007b; Charmaz, 2014; Clarke, 2005; Goulding, 2002; Hood, 2007; Reichertz, 2007). All of these dimensions are best taken into account when undertaking a grounded theory study or one's dissertation research.

Conducting grounded theory research in education

A number of grounded theory scholars have identified “core” (Bryant, 2019, pp. 49–50; Hadley, 2017, p. 59), “essential” (Birks and Mills, 2015, p. 9), “hallmark” (Guetterman et al., 2019, p. 182), “key” (Creswell and Guetterman, 2019, p. 442), and “defining” (Charmaz, 2014, p. 7; Creswell and Poth, 2018, pp. 83–84) features shared by most if not all of the grounded theory variants discussed above that together distinguish grounded theory from other qualitative methodologies. Table 1 below lists the key characteristics of grounded theory methodology alongside tips for practical application of each. (See also Glossary section above.)

The key characteristics include simultaneous and iterative data collection and analysis; the **constant comparison** method involving the making of comparisons throughout analysis at increasingly more abstract levels to develop the relationships between categories, concepts, and theory; theoretical sampling as a form of purposive sampling involving the selection of sites, participants, activities, etc., to assist in the development of theoretical categories and concepts aimed at **theory** construction; and memo-writing whereby the researcher engages in a reflective process on the data to help guide the ongoing analysis. Other important grounded theory features include delaying the literature review until analysis is already underway; theoretical saturation that signals the end of data collection when no new properties or theoretical insights are identified that contribute to the development of theoretical constructs; **theoretical sensitivity** referring to the researcher's ability to recognize and reflect upon relevant empirical data during analysis; and the end or byproduct of the research represented by the development of a substantive or formal theory, explanation, or model to explain the studied phenomenon. As is the case with all qualitative approaches, the grounded theory coding process is at the heart of methodological operations: coding is the data analysis process of applying descriptive labels to data or data sets for analytic purposes in order to organize data at increasingly higher levels of abstraction moving from codes, to categories, to concepts, to theory.

Table 1 Key characteristics of grounded theory research design.

<i>Characteristic</i>	<i>Description and importance</i>	<i>Tips for application</i>
Constant comparison	A time-tested analytical strategy adapted by grounded theorists that serves as a foundational pillar of the method in which emerging data are continually compared to each other at increasingly more abstract levels to further develop categories, concepts, and theory	Denzin and Lincoln (2018) advocate an idealized process whereby the researcher compares “data with data, data with code, code with code, code with category, and category with category” along the way to saturation. Gibbs (2018) offers specific memo prompts, tests, and exercises such as “waving the red flag” and “far out comparisons” to identify typical and atypical cases (pp. 67–70), and Boswell (in preparation) offers guidance on leveraging coding software for constant comparison in intersectional analyses.
Category	A type or grouping of similar or closely related codes or concepts generated through inductive data analysis. Categorizing is the process of organizing or abstracting these codes into an analytic concept or pattern	Birks and Mills (2015) present the historical usage of this term by grounded theorists (pp. 86–87) and point out that concepts, codes, and categories are often interchangeable terms in the grounded theory literature.
Coding (open, initial, theoretical, axial, selective, and focused)	The data analysis process of assigning labels and organizing data at successively higher analytical levels in grounded theory.	Charmaz (2006, 2014) and Corbin and Strauss (2014) provide examples specifically for grounded theory research that Saldaña (2021) also elaborates in his extensive overview of coding in qualitative research.
Iterative data collection and analysis	The imbricated process of collecting and analyzing data concurrently in order to leverage the analysis for more and more targeted and theoretical sampling of relevant, information-rich cases to support or refine developing theoretical categories	During ongoing transcription and coding of, for example, interview data, the researcher narrows the interview focus and continues to collect and analyze data as the theoretical model is developing.
Memoing	A well-established research strategy in the social sciences adopted by grounded theorists to refer to the researcher’s ongoing process of reflection throughout the study to help guide the emerging analysis	Types of memos include process memos, code memos, coding memos, pre-theoretical memos, lit memos, decision memos, and reflexive memos. Gibbs (2018) includes several provocative memo prompts (see especially Chapter 4) and Charmaz (2014) lists questions to ask of the data and other memo prompts (pp. 171–190).
Theoretical sampling	An often ignored but foundational form of purposeful sampling used in grounded theory referring to the ongoing selection or revisiting of participants, sites, and events directly aimed at the analytical development of theoretical categories and concepts	Researchers are encouraged to track which questions are added to an interview protocol as a direct result of previous data collection and the developing theoretical direction of the study. After each interview, researchers are also encouraged to note which of the additional questions were asked/answered in each interview in order to chart a visual representation of how data were sampled throughout the study. Draucker et al. (2007) offer an alternative visualization whereby the data objects used at each stage of sampling are tracked as input funnels (p. 1141).
Theoretical saturation	The stage of analysis that signals the end of data gathering in grounded theory analysis when no new properties are emerging that contribute to the further elaboration of theoretical constructs.	The visual representations indicated above will help the researcher “zoom in” and “zoom out” to visually see which categories are saturating.
Theoretical sensitivity	The ability and aptitude of the researcher to detect or identify multiple and variegated theoretical directions during iterative stages of data collection and analysis.	Striking a delicate balance between contemplating extant theory while also not being bound by it will enhance a researcher’s sensitivity to possible theoretical models; vast general knowledge across disciplines, paradigms, and philosophical/historical viewpoints (without strict commitments to any one ontology/epistemology) can help a researcher remain open to theoretical positions and dispositions that help to ground a theory.
Theory	Adapted by grounded theorists to represent a substantive or formal explanation or model of the central phenomenon being studied that emerges from data analysis throughout the research process	Saldaña (2021) provides helpful guidance on how second cycle codes can be joined by verbs that then help to flesh out the theoretical model, based on the stated relationships between categories (pp. 347–359) such as <i>X contributes to Y</i> , or <i>A varies when B</i> .

Adapted from [Guetterman et al. \(2019\)](#).

Coding

Grounded theorists advocate different forms of coding from open, initial, axial, and substantive coding to increasingly selective, focused, or theoretical techniques used to develop the emerging theory. Open coding refers to the first phase of coding procedures where the analyst assigns codes/descriptors to text passages. Charmaz (2014) uses the term initial coding for this first phase of analysis and advocates using gerunds and line-by-line coding of text passages. Axial coding denotes Strauss and Corbin's (1990, 1998) second phase or type of coding where the researcher views a category as an axis and delineates relationships around it using a coding paradigm. Selective coding is the process of choosing a central or core category and then systematically relating it to other categories (Strauss and Corbin, 1990, 1998). Focused coding is the process of identifying the most frequent or important codes to further test against the data to arrive at analytical or focused codes that serve as the basis for theory development (Charmaz, 2014). Theoretical coding is the process by which substantive theoretical codes are related to the core category that emerges through data analysis (Glaser, 1978, 1992). As we have discussed, these coding procedures differ in the various grounded theory sub-approaches. Additionally, coding schema are almost as numerous and diverse as the data sets they are meant to analyze: Saldaña (2021) outlines the rationale for, and applications of, more than 25 coding methods. This is generally an intuitive process whereby potential grounded theorists experiment with different coding techniques as they learn to master strategies that are most effective to accomplish their research goals (see Bryant, 2017, for a detailed discussion of coding and how doctoral advisees approached this process).

A number of scholars have outlined the basic procedures or strategies to conduct grounded theory analysis, each of them incorporating the core features outlined above (Birks and Mills, 2015; Bryant, 2017; Charmaz, 2014; Creswell and Guetterman, 2019; Creswell and Poth, 2018; Hadley, 2017; Strauss and Corbin, 1990, 1998) and in many ways adhere to the general structure of conducting qualitative research (see Babchuk, 2019). The researcher must first address if grounded theory is an appropriate (or the most appropriate) design to address the research problem. Grounded theory has historically been the methodology of choice when the researcher is interested in developing a theoretical framework or explanation of a basic social or social-psychological process, often when there is little known about the central phenomenon of study. In consideration of the researcher's own positionality, their epistemology, and their theoretical framework and its potential fit with the research question, the researcher may benefit by selecting one of the sub-approaches to grounded theory outlined in this article and follow the suggestions associated with it in the design and conduct of the research.

Theoretical sampling and theory development

One core feature of grounded theory that helps distinguish it from other qualitative approaches is the process of theoretical sampling (discussed above) guiding the strategic selection of sites, individuals, and events to further the development of theoretical categories and concepts to enrich theory building. Draucker et al. (2007) provide comprehensive details on both the principles of theoretical sampling as well as examples from their own studies. An additional feature attributed to grounded theory research that has been widely incorporated across qualitative designs is **maximum variation** sampling. This procedure involves the selection of a range of participants, groups, sites, or activities that differ on selected dimensions that are germane to the research question (e.g., age, location, past experience), and it enables the researcher to develop a more complete picture and elucidate the boundaries of the studied phenomenon.

Number of interviews

A burning question in grounded theory methodology, rooted in quantitative traditions and the need for a study to be adequately *powered* is the issue of how much data, or how many instances or information-rich cases are sufficient in order for theoretical saturation to obtain. Guest et al. (2006) indicate that hindsight tends to reveal that saturation was reached after the 12th interview, with no new categories added after the sixth. However, Charmaz (2014) took issue with Guest et al.'s approach, arguing that they were aiming to saturate data, not categories (p. 106). The saturation of categories rather than data constitutes an important distinction between grounded theory and other qualitative approaches as the researcher strives to saturate categories in the development of theory versus saturation of data per se. Creswell and Poth (2018) recommend 20–30 participants for a grounded theory study whereas some suggest as many as 50 (Birks and Mills, 2015). In Guetterman (2015) oft-cited analysis of sampling strategies employed in contemporary qualitative research studies, he found that the mean sample size in his article pool was 59 for those researchers who employed grounded theory (p. 12).

Beyond mere numbers, Malterud et al. (2016) advance a concept of “information power” (p. 1753) which determines saturation thresholds for saturations based on a combination of the study's particular aims, sample heterogeneity, the richness of interview data and the specific analytic strategies employed (p. 1756). There is thus no “one size fits all” prescription for achieving saturation through sample size. Sample size is a matter of some debate in grounded theory, but the researcher should aspire to achieve theoretical saturation to signal the end of the data collection process.

Tracking the developing theory

In order to keep a running record of the theoretical sampling process, and the progress of the developing theoretical directions, researchers may be best served to devise a convenient tool for themselves, such as the sample theory tracker in Fig. 1 below.

Fig. 1 shows a visual depiction of how developing theories can be tracked. Grounded theorists are encouraged to use some version of this tool as part of their research audit trail, as well as to have a record of how theoretical sampling decisions were

Fig. 1 Sample theory tracker.

made and whether they led to further theory development. In this image, Theory #3 (labeled as Θ_3 in the diagram) is abandoned early in the process because the researcher does not have access to enough information-rich cases from which to theoretically sample. Theories #1 and #2 are further fleshed out through the theoretical sampling process, but the former does not lead to a well-defined theory (despite saturation) and the latter does not saturate. Theory #4 is adopted in this example because it is both well-defined and saturation obtains.

Grounded theory purpose statements and research questions

At the heart of the research design is the purpose statement and central research question and sub-questions. In writing a grounded theory purpose statement it is advised that the researchers state that they are using a grounded theory approach to study a particular phenomenon, process, or action and, if possible, also indicate the participants and site(s) of the research. A grounded theory central question is a broad, overarching question that restates the purpose statement and should indicate that the research is designed to yield a theoretical explanation of the social psychological process, event, or action (see Creswell and Poth, 2018, p. 132 for a grounded theory purpose statement sample script, and p. 135 for a grounded theory central question sample script). The sub-questions break down the central question into several component parts. Table 2 provides some exemplars of grounded theory (GT) purpose statements to help guide researchers in formulating these in their research designs.

From purpose to process: grounded theory methods in practice

Data collection in grounded theory relies on methods typically employed in qualitative research including interviewing, participant observation, document analysis, audiovisual and other materials, etc. (see Birks and Mills, 2015, p. 65) but grounded theory has historically relied most heavily on interviews as the most common data collection strategy (Creswell and Guetterman, 2019; Guetterman, 2015) and Charmaz (2014) provides as the rationale the fact that interviewing allows for optimum control as to which data are generated in the course of the study (pp. 87–88). Semi-structured interview protocols typically consist of initial, intermediate, and closing or ending questions. Charmaz (2014) provides examples of these three types of questions (pp. 67–67) in a study about a life change. Typically, initial questions are open-ended and are designed to initiate the conversation about the studied phenomenon in broad, general terms. Intermediate questions delve more deeply into answering the study's research questions in more detail, whereas closing questions can serve to elaborate and revisit the information provided in the intermediate phase and provide an opportunity for the participants to raise issues that they believe were omitted or not fully developed in the previous sections and underscore important points from their perspective.

Utilizing the constant comparative method, memo-writing, and one's ability to employ theoretical sensitivity, the grounded theorist undertakes data analysis through the use of open or initial coding procedures and then more analytical intermediate and advanced coding techniques (see Birks and Mills, 2015, Ch. 6 for an excellent discussion of these processes)—as specified by the grounded theory sub-approach employed—leading to the development of a theoretical explanation or model. One also needs to take into account standards of validation (Creswell and Poth, 2018) or trustworthiness (Lincoln and Guba, 1985) well-documented in the qualitative literature (see Babchuk et al., 2017; Creswell and Guetterman, 2019). Finally, when the researcher writes the grounded theory research report it is important to rationalize the methodological decisions that have been made and

Table 2 Examples of grounded theory purpose statements.

Author	Purpose statement	GT sub-approach
Obmerga (2021, p 1)	To provide a model which would uncover the process of sensemaking of communitarian values to enrich the transformational leadership attributes of the millennial academic supervisors	Glaserian GT
Boyer-Thurgood (2017, p. 2)	To expand the explanations of and build theory about educational applications containing virtual manipulatives	Systematic GT
Chen and Phillips (2018, p. 80)	To explore the roles of influential factors among teacher–child relationships from teachers’ perspectives and to pave the way for further investigations	Constructivist GT
Ball (2013, p. 293)	To generate a theoretical model that explains how EI is used in nursing by accelerated baccalaureate nursing students	Mixed-methods GT for theory-generation
Thornberg (2018, p. 145)	In the present qualitative study, I have employed ethnographic fieldwork (Hammersley and Atkinson, 2007; Schatzman and Strauss, 1973) guided by grounded theory methods (Charmaz, 2014; Glaser and Strauss, 1967) in order to investigate the social dynamics of school bullying.	Ethnographic grounded theory

implemented; the findings (theory, model, hypothesis);-visual representations of data (tables, graphs, figures, diagrams, etc.);-limitations and scope delimitations;-the implications of the findings;-and how the study fits into the larger literature base (see Hadley, 2017, for a comprehensive discussion on writing and presenting a grounded theory, and also Strauss and Corbin, 1990, pp. 229–230). This includes appropriate disclosure of “negative cases” or discordant data (see Gibbs, 2018, p. 131 and Brewer, 2000, pp. 132–33, as well as Creamer, 2018b for handling discordant data in mixed methods-grounded theory designs). Grounded theory researchers have provided guidelines for converting theses or dissertations into publishable articles (Strauss and Corbin, 1990), and identifying journals wherein to publish grounded theory work (Charmaz, 2014, p. 301; Creswell and Baez, 2021, pp. 253–256).

Evaluating a grounded theory

Several scholars have offered criteria for assessing or evaluating the quality of grounded theory research. Glaser (1978) advanced criteria of fit, work, relevance, and modifiability (pp. 4–5), while Strauss and Corbin (1990) also provided guidelines on how to evaluate a systematic grounded theory study (p. 253). Charmaz (2014) offered her own criteria for evaluating grounded theory studies including credibility, originality, resonance, and usefulness (pp. 337–338). In another thorough treatment of criteria for a grounded theory, Creswell and Guetterman (2019) provide indicators of lower and higher quality criteria relating to the utilization of the key elements of a grounded theory study (p. 455). Bryant (2017) also discusses quality criteria in detail (p. 363), as do Charmaz and Thornberg (2021) who developed a checklist of “flexible guidelines” (p. 17–18) to assess the quality of grounded theory research in general, and constructivist grounded theory in particular.

Reviews of the grounded theory literature over time indicate that those purporting to use grounded theory often do not attend to the suggested procedures recommended by grounded theorists, or selectively or partially use grounded theory methods and/or don’t report specific details of their methodology in their published work (Babchuk 1996, 1997, 2008, 2011; Guetterman et al., 2019). On this basis, several researchers have offered recommendations for educators interested in conducting grounded theory research (Babchuk, 1997, 2008, 2011; Bryant, 2017; Guetterman et al., 2019). These include acquiring a basic understanding of qualitative methods/theory and research including differences between quantitative and qualitative approaches as well as similarities and differences of several of the popular contemporary approaches (see Creswell and Poth, 2018 or Merriam and Tisdell, 2016). The aspiring grounded theorist should also read key works in the grounded theory tradition (see *Recommended Readings Texts* section below) to acquire an understanding of this methodology and its variants to help inform choices when selecting a sub-approach for the research. We recommend selecting one of the grounded theory variants discussed in this article and following the guidelines offered by the proponent(s) of the sub-approach. Bryant (2017) argues for a less methodologically dogmatic view that encourages students to figure out their own interpretation and application of the grounded theory methodology when conducting their research whereas Holton and Walsh (2017) advise the novice grounded theorists to develop a research stance.

Whereas some researchers choose an à la carte approach to grounded theory—adhering to only those methods that are attractive or convenient for them—attending to the full complement of grounded systematic and rigorous procedures, as well as the key characteristics outlined above, better enables the researcher to more fully develop categories, concepts, and theory. It may also be beneficial to delay an extensive use of research literature until one is analyzing and writing up the findings and developing the theoretical framework. As in all qualitative research, the researcher needs to position oneself in the study and clearly articulate this to the reader. Moreover, the researcher is not just another consideration to be taken into account but an active participant in the totality of the

research process from initial design to the dissemination of the research to a broader audience. It is important that the analyst be as transparent as possible and provide as much detail as logistically feasible so that the reader can best understand the design decisions that were made.

Examples of grounded theory studies in education

There is a robust literature base employing grounded theory methodology to study educational issues and topics (see Babchuk, 1997; Birks and Mills, 2015; Bryant, 2017; Charmaz, 2014; Creswell and Guetterman, 2019). Following Glaser and Strauss (1967) and Glaser's (1998) classic grounded theory approach, Bahng and Lee (2017) utilized the constant comparative method and open, selective, and theoretical coding practices to develop themes and theory explaining the professional journey of "elementary teacher candidates (ETC) both as learners and as teachers by exploring their learning experiences and practices" (p. 225) regarding their use of a virtual reality platform. Another example comes from Creswell and Brown (1992) who, drawing upon Strauss and Corbin (1990) grounded theory procedures of open, axial, and selective coding, interviewed 33 department chairpersons to develop a model specifying their roles in enhancing faculty research productivity.

Also relying upon Strauss and Corbin's (1998) systematic grounded theory, Komives et al. (2005) developed a conceptual model to explain the development of leadership identity among college students that illustrated processual change from a leader-centric view to a more collaborative and relational process over time. Stating they were using a constructivist grounded theory approach, Williamson et al. (2012) employed Strauss and Corbin's (1998) open, axial, and selective coding procedures to develop a substantive theoretical model of meaning making among high functioning 7–13-year-old children with autism spectrum disorder. Their grounded theory yielded three reading comprehension profiles explaining this process.

Thornberg (2018) employed Charmaz's constructivist grounded theory—utilizing theoretical sampling, constant comparison, memo-writing, and initial, open, and theoretical coding—in an ethnographic study of three urban public primary schools in Sweden. In what could be classified as a grounded theory ethnography (see below), this researcher provided an interpretative portrayal of school bullying at the macro, meso, and micro levels. In our final example in this section, Vaccaro et al. (2018) followed Charmaz (2014) initial, focused, and theoretical coding procedures, theoretical sampling, and theoretical saturation to develop a multifaceted grounded theory model of the purpose development process among college students with a wide array of disabilities. These researchers documented the developing narrative sense of self among participants explaining how these individuals negotiated this process.

Future directions

The use of grounded theory continues to grow across disciplines and subject areas, having been incorporated by scholars and practitioners in a wide array of fields to explore myriad subject areas. Earlier in this article we presented four contemporary variants or sub-approaches of grounded theory research. Two additional variants of grounded theory are ethnographic grounded theory, which we believe holds great potential for future research, and mixed methods-grounded theory, which is already widely adopted and rapidly gaining traction as the mixed methods movement has become increasingly embraced by scholars in education and the social and health sciences.

Various forms of comparative analysis and emergent theorizing have a rich and long history in ethnographic research and are well documented in the literature (see Jaccard and Jacoby, 2009; Salzman, 2011). In *The Discovery of Grounded Theory* (1967), Glaser and Strauss made explicit ties between constant comparison, grounded theory, and ethnographic research (Babchuk and Hitchcock, 2013; Glaser and Strauss, 1967). Here, Glaser and Strauss incorporated a comparative analysis accounting checklist to systematically review historical applications of the comparative method in published research by sociologists and anthropologists. Using criteria outlined in this checklist, they assigned comparative research studies from these disciplines into one of three categories: (1) Verification of Theory, (2) Assumed Verification plus Limited Generation, and (3) Comparisons for Generation. The third category represented examples of comparative research most akin to their grounded theory approach. These included such classics as Goffman's (1959) *Presentation of Self in Everyday Life*, Etzioni's (1961) *A Comparative Analysis of Complex Organizations*, Geertz (1963) *Peddlers and Princes*, and, most notably, Evans-Pritchard's (1937) *Witchcraft, Oracles, and Magic among the Azande* (Babchuk and Hitchcock, 2013; Glaser and Strauss, 1967).

Ethnographic grounded theory

Since the publication of *The Discovery of Grounded Theory* (1967) some researchers have underscored potential advantages of blending traditional features of ethnography and grounded theory's theory-methods package to be utilized for ethnographic and cross-cultural research (Aldiabat and Navaenec, 2011; Babchuk and Hitchcock, 2013; Barnes, 1996; Charmaz, 2006, 2014; Charmaz and Mitchell, 2001; Gales, 2003; Goulding, 2002; Pettigrew, 2000; Phelps and Horman, 2010; Sheridan and Storch, 2009; Timmermans and Tavory, 2007). Systematically combining elements of grounded theory and ethnography can be envisioned as representing a new hybrid qualitative approach. We have chosen to use the label **ethnographic grounded theory** herein to represent this hybrid approach.

Ethnographic grounded theory has historically been referred to in the grounded theory literature as "grounded ethnography" (Battersby, 1981, p. 93), "grounded theory ethnography" (Charmaz, 2006, p. 22), and "grounded theory in ethnography" (Charmaz, 2014, p. 35) and has been effectively utilized across disciplines and subject areas. Lauding the potential benefits of such

a merger, Battersby (1981) argued that grounded theory can “extend the limited theoretical component of ethnography” (p. 259), while Pettigrew posited that merging grounded theory and ethnography yields a level of detail “unavailable from other methodologies” (p. 260). Similarly, Sheridan and Storch (2009) upheld the potential of grounded theory to make an important contribution to intercultural research.

In the most comprehensive treatment of ethnographic grounded theory, Charmaz and Mitchell (2001) and Charmaz (2006, 2014) posited that this hybrid approach, by way of the and the constant comparative method, enables ethnographers to systematically compare data throughout the research rather than after data collection, use data to compare with emerging categories, demonstrate relationships among concepts and categories, achieve greater active involvement by ethnographers in the research process, and help elevate descriptive data analysis to veritable explanation and theory building. Moreover, Charmaz (2014) posits that the approach prevents ethnographers from uncritical acceptance of the viewpoints of participants, fieldwork lacking in direction or focus, and an over-reliance pre-existing etically derived concepts or categories. In effect, grounded theory ethnography has the potential to extend the theoretical component of ethnography that has often relied heavily upon description and the use of a priori theory. It can help shift analysis from description to explanation and theory building while reducing ethnocentrism by allowing for the emergence of culture-specific concepts rather than the dependence or over-reliance on pre-determined hypotheses or frameworks of the discipline (Babchuk and Hitchcock, 2013; Spradley, 1980). Thornberg (2018) leveraged ethnographic fieldwork including interviews and observations to ground a theory of bullying in Swedish public primary schools. Bartholomew, in a series of publications (Bartholomew, 2017, 2018; Bartholomew and Genz, 2019) has employed ethnographic grounded theory to study to mental health issues among the Awambo of Northern Namibia.

Grounded theory and mixed methods designs

In *The Discovery of Grounded Theory* (1967) Glaser and Strauss also emphasized the potential for grounded theory to be used with both quantitative and qualitative data. Since that time, scholars have argued for the effectiveness of grounded theory to be used in pluralistic designs including multimethod qualitative research and mixed methods research applications (Babchuk, 2015; Birks and Mills, 2015; Creamer, 2018a,b, 2021; Holton and Walsh, 2017; Johnson et al., 2010; Johnson and Walsh, 2019; Charmaz, 2014; Guetterman et al., 2019; Walsh, 2015). Mixed methods-grounded theory (MM-GT), a term coined by Johnson et al. (2010), pragmatist grounded theory (Babchuk, 2015), and mixed grounded theory (Johnson and Walsh, 2019) are roughly synonymous labels referring to the use of mixed methods in the service of grounded theory research. Based on Johnson et al. (2010) pioneering work, and that of Guetterman et al. (2019), we will use the term *mixed methods-grounded theory* in this article.

Mixed methods, or what has been called the third major research paradigm (Johnson and Onwuegbuzie, 2004), involves the systematic integration of quantitative and qualitative data to achieve a deeper understanding of the studied phenomenon than could be realized through a single method or research strand alone (Creswell and Plano Clark, 2018; Guetterman et al., 2019; Plano Clark and Ivankova, 2016). Traditionally, in a mixed design, qualitative and quantitative strands are strategically sequenced and combined in a mixed methods study through *integration* at the design, procedural, and/or interpretive levels (Fetters et al., 2013). Mixed methods designs have been categorized—in one widely used typology—into the three core designs of *explanatory sequential* (initial quantitative strand followed by a qualitative strand), *exploratory sequential* (initial qualitative strand followed by a quantitative strand), and *convergent* (quantitative and qualitative strands conducted independently, after which findings and results are merged), a typology explicated in detail by Plano Clark and Ivankova (2016) as well as Creswell and Plano Clark (2018). Here also exist advanced designs that showcase more complex configurations such as embedding, or more nuanced methodologies such as mixed social justice or action research designs (Creswell and Poth, 2018; Guetterman et al., 2019; Lingard et al., 2008; Plano Clark and Ivankova, 2016). Consistent with grounded theory’s historical goals to be used for either theory generation or theory verification, MM-GT designs can be configured to accomplish both these aims within one study: to use a grounded theory strand to generate or develop theory that is subsequently tested in a quantitative strand, or to follow a quantitative strand with a grounded theory one that plumbs for further detail on the preceding quantitative results.²

MM-GT offers many advantages for researchers interested in applying mixed methods approaches to the study of social phenomena. This approach is often characterized by interdisciplinarity and team collaborations whereby multiple researchers blend their perspectives and skillsets to achieve a “both-and” advantage in their studies (Johnson and Walsh, 2019, p. 524). According to Charmaz (2014), “grounded theory can contribute to each form of mixed methods research” and (p. 324) “disparate findings, particularly between interpretive understandings and measurable responses, can be significant and certainly merit further inquiry” (p. 325). MM-GT’s unique contribution to social research is the many options it features for combining multiple logics of inquiry including induction, abduction, and deduction—in an elegant alignment with grounded theory’s embrace of these multiple logics. Team grounded theory research can especially accommodate these logical approaches provided that they are deliberately harmonized and do not pose ontological or epistemological conflicts for diverse researchers combining their efforts on a jointly conceived project. Other advantages of employing MM-GT research over qualitative grounded theory used in isolation include the possibility of increasing funding opportunities, as funding agencies may prioritize quantitative research over stand-alone qualitative designs. In

²There are also instances where a quantitative grounded theory strand can be combined with a qualitative one as part of a mixed study. Johnson and Walsh (2019) offer several permutations including concurrent QUAN and QUAL GT strands, an exploratory sequence in which a QUAL GT strand precedes a QUAN GT strand, or an explanatory sequence in which QUAN GT leads to a QUAL GT phase, among other designs. Any MM-GT design counts this combination among its affordances, but the sequencing should be determined by the specific aims of the researchers.

a similar vein, mixed methods can enhance credibility of qualitative research in fields that are historically quantitative in nature, can be particularly appealing to quantitatively-trained researchers interested in expanding their toolkit as grounded theory has historically been considered more rigorous and systematic than most other qualitative approaches, and can bolster substantive or formal theory development through generation and testing of theoretical propositions in the same study (Babchuk, 2015; Guetterman et al., 2019). Along these lines, Creamer's (2018b) identified advantages of MM-GT include constructing a multilayer theory, addressing discordance between qualitative findings and quantitative results in the development of a more complex theory, and both generating and testing a theory within a study.

There are some special considerations when undertaking MM-GT studies. Researchers must each commit to a thorough and reflexive exploration of their positionality in relation to participants, data, and other aspects of the research process. These efforts toward positioning, when considering ethics in grounded theory research, are specialized in grounded theory, owing to the range of philosophies that undergird different grounded theory approaches. On an interdisciplinary MM-GT research team, it behooves each researcher to authentically and continually recalibrate one's positions and reflections to identify areas of possible bias as well as "dangers unseen and unforeseen" (Milner, 2007). The Glaserian notion that "themes emerge" inductively from the data on their own, for example, poses philosophical challenges to interpretivists who approach the research with an expanded view of the role of the researcher as an instrument of inquiry. Given that "mixed methods may divide, collide, or cohere" (Charmaz, 2014, p. 324) under the best of circumstances, special care must be taken by mixed research teams intersecting grounded theory with other designs in order to clearly and appropriately imbricate multiple ontologies, epistemologies, and methodologies in a single study.

Unfortunately, however, a review of the MM-GT literature revealed that methodological details are most often incomplete or vague in this form of research offering little guidance for researchers wishing to employ this approach for their own research (Guetterman et al., 2019; Howell Smith et al., 2020). To help address this limitation, a Mixed-Methods Grounded Theory Checklist for conducting MM-GT is provided in Guetterman et al. (2019, p. 192), and Howell Smith et al. (2020, p. 201), also offer a comprehensive list of best practices for conducting MM-GT research (see also Creamer, this volume).

Mixed methods-grounded theory exemplars

Examples of mixed methods-grounded theory studies in the literature include Ball's (2013) *explanatory sequential* design in which a quantitative measure of emotional intelligence was followed by a qualitative, constructivist grounded theory strand in which the researcher conducted interviews to generate a theoretical model of how nurses leverage emotional intelligence in their work. Berman (2017) employed an exploratory sequential mixed design to first ground a theory about researchers' data management practices and then utilize the resulting themes to develop a quantitative survey instrument that measured six dimensions of researchers' behaviors. The results of both strands were integrated into a presentation known as a *visual joint display*, which is recommended for communicating the results of mixed methods research (Guetterman et al., 2015). Howell-Smith et al. (2020) also utilized an exploratory sequential instrumental development design to develop and test a theoretical model to explain how undergraduate engineering students develop an interest in pursuing a Ph.D. in engineering.

Ontological and epistemological evolution

The application of grounded theory in mixed designs showcases the inherent nature of this methodology to act in nimble ways, aligning itself with many and variegated epistemologies and ontologies. Grounded theory is not, however, infinitely flexible and if it were, it could stand to lose its rigor and value. One can imagine that a classic, Glaserian grounded theory where "themes emerge" of their own accord—with the grounded theorist playing the role of neutral observer—would be ill fit to a project resting on a more relativist or postmodern view of reality and the role of the researcher. Likewise, constructivist notions—take to their logical extreme—may refute the existence of a shared set of observable facts. This poses an acute ontological dilemma (Boswell and Babchuk, 2022) as grounded theory enters its sixth decade and transforms—within reason—to adapt to new and renewed ways of knowing, and other seeing the world. In particular, combining constructivist GT with particular critical theoretical applications presents both challenges and opportunities for the future of this methodology.

Critical theoretical applications

Oliver (2012) makes the case for a critical realist brand of grounded theory, seeking to blend the best of both approaches toward the emancipatory aims of critical social work while embracing realist ontologies of social ills. Hadley (unpublished manuscript) outlines what might be at stake for grounded theorists—particularly constructivists—to explore ontologies and epistemologies above and beyond those that have undergirded the main grounded theory sub-approaches. For instance, a critical realist approach would have researchers differentiate ontology from epistemology, espousing a mind-independent reality that can be fallibly known. This has implications for grounded theory methodologists because it sets up a question as to whether or not one must be constructivist in belief, for example, in order to rigorously apply constructivist grounded theory methods. While embracing multiple ways of knowing and deep reflexivity, constructivist grounded theory could be rightly judged for leaning too heavily toward multiple social realities, and away from empirical facts about systemic forms of oppression and abuses of power, as centered in critical theoretical applications.

In her argument that constructivist grounded theory is well poised toward social justice aims and aligned with critical theories, Charmaz (2020) praises her sub-approach as better attending to researchers' reflexive positioning in relation to participants, particularly those from marginalized or minoritized backgrounds. She argues that research in the public sphere benefits from the

increased scrutiny of the role, possible biases, and background of the researcher. Indeed, constructivist grounded theory augments the qualitative imperative to acknowledge the researcher as “instrument” of inquiry (Creswell, 2014, p. 185). But reflexivity can also be taken to an extreme that reduces the usefulness of the grounded theory generated (Gibson, 2007, p. 440). When challenged as to whether critical inquiry can be adequately accomplished through the interpretivist tradition, Charmaz signals her disagreement with scholars advocating a critical realist ontology (2020, p. 174). In order for grounded theory to continue to grow and realize its full potential, however, it must accommodate the empirical realism that inheres in a specific critical framework, critical race theory.

Critical race theory and grounded theory methodology

Critical race theory (CRT) reshaped legal studies in the United States in the 1970s and 80s, endorsing an empirical realism that forces individuals and institutions to attend to the systematic results of raced, classed, gendered, and ableist assumptions operating beneath social agreements large and small. In the ensuing years, CRT was introduced to the field of education by Ladson-Billings and Tate (1995), who argued that educational inequalities in the US are not surprising or unexpected, and in fact that these gross inequities are “a logical and predictable result of a racialized society in which discussions of race and racism continue to be muted and marginalized” (p. 47). While Hadley (2017, 2019) advocates for a critical grounded theory and Charmaz (2011) espoused social justice aims, neither directly applies CRT into a grounded theory methodology. Grounded theory must be prepared to embrace the crucial antiracist work that requires CRT-informed methodologies both quantitative and qualitative. The next “turn” in the grounded theory universe may prove to be the *antiracist turn*.

Malagon, Pérez Huber, and Velez telegraphed this conversation in 2009, concluding that, “CRT scholarship must not only direct energy to substantive knowledge generation but must also reveal how an anti-oppressive research process can aid in achieving our central goals for racial and social justice” (p. 269). A decade later, Vanidestine and Aparicio (2019) used what they termed a “social justice approach to grounded theory” to study race and racism. What remains to be seen is how education researchers and other social scientists will resolve the ontological conflicts between the interpretivist disposition toward relativism and CRT’s need for an empirical realism that acknowledges shared facts of systemic racism and what Coates (2017) calls “the bitter calculus of oppression” (p. 100). Some promising integrations include grounded visualizations that display *situated knowledges* as well as a process known as “ground truthing” (Vélez and Solórzano, 2019)—both tools of critical race spatial analysis and both poised to bridge the history of grounded theory with the future of innovative data collection and sharing.

Conclusion

Grounded theory has been considered the most popular contemporary qualitative research methodology. Although it can also be used for quantitative applications, it is often selected as the qualitative method of choice in the blossoming third research movement of mixed methods research. Harkening back to the epistemological “paradigm wars” relating to an earlier era of qualitative research debate (Denzin and Lincoln, 2018), conflicting interpretations of the grounded theory methodology and its application are less acute than they were in earlier decades with researchers instead focusing on their own potentially successful interpretations of the grounded theory methodology rather than further politicizing these arguments (Bryant, 2017). Grounded theory has grown exponentially in its use across disciplines, settings, and problem areas over the past fifty plus years and it continues to hold great potential for the future of educational and social research. The research methodology literature owes a great intellectual debt to the genius of Barney Glaser and Anselm Strauss as well as those that continue to carry on the grounded theory tradition.

Acknowledgments

We would like to thank Dr. Gregory Hadley, Dr. Timothy C. Guetterman, and Analay Perez for their contributions to this manuscript.

Dedication: We dedicate this article to the first author of the last edition’s article on grounded theory of this Encyclopedia, Kathy Charmaz, whose guidance and influence has been immeasurable on a generation of grounded theorists including the co-authors of this manuscript.

Narrative inquiry on the research landscape

Narrative inquiry, first named in [Connelly and Clandinin \(1990\)](#), *Stories of Experience and Narrative Inquiry*, is a qualitative methodology in the field of social science research ([Clandinin, 2007](#); [Pinnegar and Daynes, 2007](#)). Narrative inquirers understand that “people shape their daily lives by stories of who they and others are and as they interpret their past in terms of these stories. Story ... is a portal through which a person enters the world and by which their experience of the world is interpreted and made personally meaningful” ([Connelly and Clandinin, 2006](#): 375). Narrative inquiry is both a way of thinking about experience and a methodology for the study of experience.

Foundational to narrative inquiry is [Dewey’s \(1938\)](#) conception of experience, that is, that experience is “a changing stream that is characterized by continuous interaction of human thought with our personal, social, and material environment” ([Clandinin and Rosiek, 2007](#):39). Further to this, it is important to recognize that a narrative view of experience is “not only on individuals’ experience but also on the social, cultural, and institutional narratives within which individuals’ experiences are constituted, shaped, expressed, and enacted” ([Clandinin and Rosiek, 2007](#): 42). Narrative inquirers study a person’s experience “that is storied both in the living and telling and that can be studied by listening, observing, living alongside another, and writing, and interpreting texts” ([Clandinin and Rosiek, 2007](#): 43). Thus, experience is understood as a storied phenomenon in that human beings compose lives that are shaped by their experiences within personal, familial, social, institutional, professional, linguistic, cultural, and historical narratives. A widely accepted definition of narrative inquiry is that it is a way of understanding experience, and is

a collaboration between researcher and participants over time, in a place or series of places, and in social interaction with milieus. An inquirer enters this matrix in the midst and progresses in the same spirit, concluding the inquiry still in the midst of living and telling, reliving and retelling, the stories of the experiences that made up people’s lives, both individual and social.

[Clandinin and Connelly \(2000: 20\)](#).

In this chapter, we describe the relational ontological and epistemological commitments of narrative inquiry highlighting the importance of working with relational ethics. Narrative inquiry works from a relational ontology that attends to people’s ordinary experiences in their everyday lives. We make explicit the narrative view of experience grounded in [Dewey’s \(1938\)](#) theory of

experience with its two criteria of experience, continuity and interaction, along with his understanding of situation. Dewey's theory of experience provides the theoretical foundation of the three-dimensional narrative inquiry space comprising temporality, sociality, and place. We describe the ways in which narrative inquirers engage with participants including negotiations of ongoing researcher reflexivity, the processes of living, telling, retelling and reliving stories of experience as narrative inquirers negotiate being in the field, moving from field to field texts, interim and final research texts. We detail the design elements of narrative inquiry that follow from a relational epistemology, ontology and ethics including considerations in methods that can be used as a researcher moves from field to field texts, and research texts. Woven throughout the chapter is the foundation for the touchstones or criteria for assessing a narrative inquiry. Relational ethical considerations and working with response communities are also discussed.

Ontological and epistemological considerations in narrative inquiry

Narrative inquiry has its ontological and epistemological roots in the pragmatic philosophy of educational philosopher John Dewey (1938, 1958). Drawing upon Dewey's work, narrative inquiries start with the view that experience is "the fundamental ontological category from which all inquiry—narrative or otherwise—proceeds" (Clandinin and Rosiek, 2007: 39). Experience has important ontological distinctions for narrative inquirers in that, within a Deweyan view, experience is a transaction between what each person thinks, what he or she shares with others, how she or he encounters and relates to others and the contexts in which each person lives. Experience is an active and recursive immersion in the field of experience—in life (Dewey, 1896/1975). The epistemological and ontological commitments in narrative inquiries require attention to the relational, ethical, contextual, and temporal unfolding of storied lives. A relational ontology shapes the relationship between knower and what is known, between knowing and action, between how one knows and what one knows, as well as the relationship between knowing and silence.

Narrative inquirers recognize that human beings are always in the midst of experience (Caine et al., 2013a). Part of the ontological commitment holds an understanding that to come alongside "as narrative inquirers we do not remove ourselves from our research puzzles and observe a phenomena or analyze people, but rather, we become a part of the ongoing negotiation of making meaning of experience" (Clandinin and Caine, 2013:177). Therefore, narrative inquirers understand their involvement requires that their experiences are also under study. It is not a study of the other but reflects the co-composed understandings of researchers and participants' experiences (Chung, 2018; Clandinin and Connelly, 2000). As Clandinin and Connelly (2000) wrote, narrative inquirers are "complicit in the world we study, we need to remake ourselves as well as offer up research understanding that could lead to a better life" (p. 61).

Narrative inquirers work from an epistemological perspective that reduces the distance or gap between what happens in the world and how people think about and thus know it. Knowledge arises through, and is modified by, transactions (Dewey, 1938) among thought, social context, time, and place. Knowledge is formed in response to a person actively adapting to, or engaging with, his or her environment and is thus linked to experience. Narrative inquirers build on Dewey's view that people are always positioned on a continuum of experiences, and emphasize that "each point has a past experiential base and leads to an experiential future" (Clandinin and Connelly, 2000: 2).

Thinking narratively: three-dimensional narrative inquiry space

Dewey's (1938) criteria of experience-continuity and interaction enacted in situations-provides the foundation for attending to experience. The criterion of continuity (Dewey, 1938) highlights the unfolding temporality of experience with an understanding that past experiences live in, and shape, future experiences. Continuity points toward how "independent of desire or intent, every experience lives in future experiences" (27) and that "every experience both takes up something from those which have gone before and modifies in some way the quality of those which come after" (35). In this transactional view of experience, relations are built "between a human being and her environment—her life, community, world" (Clandinin and Rosiek, 2007: 39). The conception of reality and knowledge is relational, temporal, and continuous between researchers and participants. Dewey's (1938) other criterion of experience, interaction, which is inseparable from the concept of situation, highlights that "an experience is always what it is because of a transaction taking place between an individual and what, at the time, constitutes his environment" (43).

Narrative Inquiry is conceptually grounded in Dewey's (1938) notion of the dynamic interplay and interaction of the two criteria. This provides groundings for what narrative inquirers name as the three-dimensional narrative inquiry space with its dimensions of temporality, sociality, and place. Attending to experience within the three-dimensional space allows narrative inquirers to study the complexity of the relational composition of people's lived experiences, in the past and in the present, as well as to imagine the future possibilities of these experiences. Within the three-dimensional space, researchers look simultaneously backward and forward (temporality), inward and outward (sociality), with attention to place(s).

Within the temporal dimension, attention is directed toward the past, present, and future of people, places, things, and events, under study. The importance of temporality in narrative inquiry is informed by philosophical views of experience where the "formal quality of experience through time is [seen as] inherently narrative" (Crites, 1971: 291). Working from Carr's (1986) view that "we are composing and constantly revising our autobiographies as we go along" (76), narrative inquirers need to attend to the temporality of their own and participants' lives, as well as to the temporality of places, things, and events.

Narrative inquirers also attend to both personal conditions and, simultaneously, to social conditions, that is with attentiveness inward to “feelings, hopes, desires, esthetic reactions and moral dispositions” (Connelly and Clandinin, 2006: 480) and outward to the milieu, the conditions under which people’s experiences and events are unfolding. These social conditions are understood, in part, in terms of cultural, social, institutional, and linguistic narratives. Connelly and Clandinin (2006) define place as “the specific concrete, physical and topological boundaries of place or sequences of places where the inquiry and events take place” (480). Drawing on Marmon Silko (1996), experiences are always situated in a particular place or in places, and within the stories we tell of these experiences.

Working within the three-dimensional narrative inquiry space also requires that we think narratively about a phenomenon, that is, that we think within dimensions of temporality, sociality, and place. Narrative inquiries highlight the shifting, changing, personal, and social nature of the phenomenon under study. Thinking narratively about a phenomenon challenges views of a phenomenon as being fixed and unchanging throughout an inquiry. Framing a research puzzle is part of thinking narratively. Each narrative inquiry is composed around a particular wonder and, rather than framing a research question with an expectation of an answer, narrative inquirers frame a research puzzle that carries with it “a sense of a search, a ‘re-search’, a searching again”, “a sense of continual reformulation” (Clandinin and Connelly, 2000: 124).

Engaging participants in narrative inquiry

As narrative inquirers work to live out the relational aspects of each inquiry, it is important to attend to the negotiating that is required throughout an inquiry: negotiating ongoing reflexivity, negotiating living, telling, retelling and reliving stories, and negotiation within each phase of the inquiry through being in the field and composing field texts, interim research texts and final research texts, negotiating the ethical relations of being alongside as well as the work with response communities.

Negotiating ongoing reflexivity: narrative beginnings

Engaging in narrative inquiry involves ongoing reflexivity, a process that begins with composing narrative beginnings. As Dubnewick et al. (2017) show, reflexivity in the form of autobiographical narrative inquiries comes out of the relational ontological commitments of narrative inquiry. Reflexivity, in the form of narrative beginnings, is a process in which narrative inquirers write autobiographically, telling stories of earlier landscapes which may provide a frame for the personal, practical, and social justifications of why the researcher is undertaking the study. However narrative beginnings include more than telling or writing stories. Part of composing narrative beginnings involves inquiry into the stories within the three-dimensional narrative inquiry space.

The research puzzle often takes shape and becomes more visible during the construction of narrative beginnings. Greene (1995) emphasizes the importance of reflecting on earlier landscapes or what she describes as our “rememory” (82) of them. It is understood that we can never truly return to earlier landscapes, however, we are able to narratively reflect on them from our present, perceived vantage point. Greene illuminates the importance of returning to earlier landscapes as she notes, “we can only become present to them by reflecting on them” (1995: 73).

Understanding life as narrative led Bruner (2004) to posit that “the stories we tell about our lives ... [are] our ‘autobiographies’” (691). Yet, narrative inquirers understand that telling stories is not an untethered process. How people tell their stories and what their stories tell is shaped by “cultural conventions and language usage ... [and] reflect the prevailing theories about ‘possible lives’ that are part of one’s culture” (694).

Narrative beginnings are a kind of autobiographical narrative inquiry similar to autoethnographic inquiry. Autobiographical narrative inquiry, “the interpretation and writing of the personal past ... is ... a product of the present and the interests, needs, and wishes that attend it. This present, however—along with the self whose present it is—is itself transformed in and through the process” (Freeman, 2007:137–138).

Negotiating living, telling, retelling and reliving stories of experience

Within narrative inquiry we work with four key terms: living, telling, retelling, and reliving. We live out stories and then tell stories of our living. In this process, inquirers continue to live their stories, even as, over time, they tell stories of their experiences. While most narrative inquiries begin with telling stories, that is, with a researcher interviewing or having conversations with participants who tell stories of their experiences, “a more difficult, time-consuming, intensive, and yet, more profound method is to begin with participants’ living because in the end, narrative inquiry is about life and living” (Connelly and Clandinin, 2006: 478).

We also retell stories through processes of inquiring into the lived and told stories. Narrative inquirers engage in inquiry with themselves and participants as they retell their stories. As we retell our lived and told stories, there are possibilities for change, that is, for reliving the retold stories. Through retelling and reliving stories of experience, we begin to restory ourselves and imagine how we might live differently in the world, and perhaps “shift the institutional, social, and cultural narratives in which we are embedded” (Clandinin, 2013: 34).

Negotiating being in the field

Narrative inquiry is a process of entering into lives in the midst of each participant's and each inquirer's life. Narrative inquirers intentionally come into relation with participants and come alongside another's life while negotiating an ongoing relational space with participants; "a relational space we call the field.... In this way, there are possible starting points for narrative inquiry: listening to individuals tell their stories and living alongside participants as they live and tell their stories" (Clandinin, 2013: 45).

What this draws attention to is the importance of acknowledging the ongoing temporality of experience when it is understood narratively. Engaging in narrative inquiries is a recursive process of being in the field, composing field texts, drafting and sharing interim research texts, and writing research texts. Lessard et al. (2020) point to the importance of being in relation throughout the research process, that is, to ways in which we continue to puzzle alongside each other and alongside participants. Without continuing to puzzle alongside each other and participants, we are in danger of becoming certain and of losing our inquiry edges. In becoming certain, we lose "the value of trying to see otherwise, of seeing on the peripheries of what is possible." Part of narrative inquiry is an openness to going into the field without tightly rehearsed scripts. This openness to otherwise "often bumps up with other types of research that may prefer specific structured questioning techniques, narrow timelines, and ideas of how to engage" (4).

Negotiating from field to field texts

Being in the field involves settling into and attending to the temporal unfolding of lives. When we engage with participants in telling their stories, Sarris reminds us that stories are often not shared in "chronological sequence" (1993: 1). In living alongside participants, hooks (1997) cautions us that people's lived and told stories are not linear—they do not necessarily "move from point A to point B" (24). The narrative qualities of lived and told stories arise from the temporal nature of experience in which people are simultaneously participants in, and tellers of, their life stories (Carr, 1986).

There are multiple ways to create field texts (data) from studying experiences of participants and inquirers in a narrative inquiry. Field texts can include transcripts of conversations, field notes, stories, memory-box artifacts, photographs, documents, art work, journals, and other texts that are composed by narrative inquirers and participants to represent aspects of lived experience. Whether narrative inquirers are listening to participants' told stories or living alongside participants as their lives unfold in particular contexts, interpretation is an essential, ongoing aspect. Being attentive to the relational aspects of working with participants within the conceptual frame of the three-dimensional space requires that narrative inquirers and participants acknowledge that they are always interpreting their pasts from their present vantage points.

Negotiating from field texts to interim research texts

Bateson (1989) writes, "Dissection is an essential part of scientific method, and it is particularly tempting to disassemble a life composed of odds and ends, to describe the pieces separately" (10). Within narrative inquiry we understand experience within the wholeness of a life lived and told rather than as fragments of a person's life. We work to resist the temptation to "disassemble a life." Gergen (2003) also cautions that an "analytical method of deconstructing stories into coded piles" could undermine "the aims of the research" (272) by directing attention away from thinking narratively about experience.

Through attending to dimensions of temporality, sociality and place, narrative inquirers and participants shape field texts into interim research texts. To move from field texts to interim research texts, a narrative inquirer begins by looking at all field texts as an "archival task," that is, they ensure they have "read and reread all the field texts and in some way sorted them" (Clandinin and Connelly, 2000: 131). This movement from field texts to interim research texts is a time marked by tension and uncertainty.

While some interpretations are underway as the inquiry is lived with participants in the field, at some point there is a move away from the intensive contact with participants. In composing interim research texts, narrative inquirers continue to think narratively, that is, positioning field texts within the three-dimensional inquiry space. As inquirers continue to compose interim research texts, usually called narrative accounts, they may discern resonant threads, or patterns, that reverberate across the lived and told stories. With this intentional focus on threads or patterns, inquirers can follow "particular plotlines that threaded or wove over time and place through an individual's narrative account" (Clandinin, 2013: 132).

Interim research texts are often partial texts. Bringing back interim research texts to further negotiate with participants around unfolding experiences is part of the process of composing interim research texts. This ongoing dialog with participants can lead to more intensive work with participants if further field texts are needed in order to compose a more complex account of the participants' experiences alongside the researcher.

Negotiating from interim research texts to final research texts

As narrative inquirers move from interim research texts to composing final research texts, there is another level of negotiation as the inquirer works to write the most telling aspects of the experiences. Often what is shared in research texts is only a portion of the overall data. These negotiations are within the inquirer as s/he looks at the experiences represented in the interim research texts as well as to the literature around the phenomenon.

Working with metaphors, creating visual and textual collages, found poetry, word images, art work, conversations, archival and purpose-taken photographs and other artifacts, narrative inquirers create research texts in order to show the complex, multilayered, storied experiences of participants and inquirers. Final research texts are the texts we make “visible to public audiences, unknown audiences who may be far removed from the lived and told experience of participants” (Clandinin, 2013: 50). As narrative inquirers compose final research texts, they return to the personal, practical, and social justifications of the work.

In narrative inquiry, “ethical matters need to be narrated over the entire narrative process” (Clandinin and Connelly, 2000: 170). In honoring the relational aspect of each inquiry, final research texts are shared with participants whenever possible but are not composed with them. Clandinin and Connelly (2000) speak to narrative inquirers’ ethical responsibilities to, and with, participants throughout the research process. Ongoing negotiation with participants around interim research texts allows narrative inquirers to create final research texts that critically represent narrative inquirers’ and participants’ experiences while also maintaining each person’s integrity and their relationships into the future. When, for example, a narrative inquiry makes visible the bumping up of participants’ lives with dominant cultural, social, and institutional narratives, working with fictionalization in research texts can enable stories to be told without harming participants’ lives or the relationships composed between narrative inquirers and participants.

Signature and voice both shape research texts. We attend carefully in order not to allow the inquirer’s voice to write over participants’ voices in the final research texts. Issues of audience are also important as narrative inquirers reflect on the purpose of their research. Final research texts are “shared in ways that help readers question their own stories, raise their own questions about practice and ... to foster reflection, storytelling and restorying for readers (Connelly and Clandinin, 1990: 20).

Negotiating working with response communities

It is often helpful for narrative inquirers to participate in response communities where, alongside other narrative inquirers as well as people from diverse backgrounds, they share and respond to one another’s thinking or writing in progress, in ways that are attentive to the lives being represented. Response communities may profoundly shape each aspect of a narrative inquiry, noting the importance of members being attentive to “who we each are and are becoming in the research and how relationships shape how we come to conceptualize research puzzles as well as how we live alongside research participants. How we begin shapes the unfolding of our inquiries, it shapes what is possible” (Lessard et al., 2020: 2).

There are seven interwoven features of response communities (Caine et al., 2018) that are necessary for a response community to be a space that sustains, allows for the giving back of stories, and allows researchers to become visible in the ways we live out our stories as people in relation. Within narrative inquiry, response communities are embedded within the social narratives of researchers’ lives and help researchers understand themselves “within what Arendt (1958) would call public spaces. Response communities help us face the world in a different way, one that makes different social, political relationships possible” (Caine et al., 2020: 5). Response communities also help make visible other considerations that narrative inquirers need to attend to when coming alongside participants. As well, response communities work to caution narrative inquirers about the importance of slowing down, of continuing to find ways to be in relation, and of working to develop relationships with participants as ones marked by a sense of mutuality, respect, and reciprocity. In order to slow down and move in more relational ways, “it is important to recognize that the questioning of who we are in each situation, in each relationship, and in each place is part of the ways narrative inquiry is lived” (Lessard et al., 2020: 4).

Before, during, and after research projects end, narrative inquirers continue to engage in conversation with response communities and to stay in relation with former participants. While it matters how we begin a narrative inquiry, it also matters how an inquiry shapes forward looking stories for participants and for inquirers. The relational process of engaging in a narrative inquiry alongside participants carries a responsibility and understanding that “despite a focus on particular phenomena we are interested in understanding, we do not lose sight of each other and of how our lives are shaping the research and how the research is shaping us (Chung 2018; Clandinin et al., 2018)” (Lessard et al., 2020: 2).

Design considerations

There are important considerations in designing and engaging in narrative inquiry. It is crucial that narrative inquirers are able to articulate the purposes and justifications for their research. The criteria for judging narrative inquiries, what are termed the touchstones, will also be explored as part of the research design considerations.

Justifications for narrative inquiry

In narrative inquiry it is important to think about justifying the research in three ways—personal, practical, and social. The researcher’s justifications for engaging in the research are embedded in the narrative beginnings which provide the rationale of how, and why the narrative inquirer came to their research puzzle. At the end of the study, the researcher returns to the justifications to retell, relive, and re-imagine new possibilities as they think with the stories lived and told by participants. Below is a more detailed description of each justification.

Personal justification

Narrative inquirers begin with personal justifications, that is, by justifying the inquiry in the context of their own life experiences and what personally brings them to their research puzzle. It is important to inquire into who inquirers see themselves as being, and becoming, within the inquiry in order to be wide awake (Greene, 1995) to the experiences of those we come alongside. The narrative inquirer positions oneself as part of the inquiry, using “I” to share their personal justification. Narrative inquiries including theses and dissertations begin with autobiographical stories lived and told by the researcher which are guided by the three-dimensional Inquiry space. The personal narratives and reasons which have inspired or provoked the narrative inquirer for undertaking the research are shared at the onset and returned to at the end of the study. For instance, in Chung’s (2016) narrative inquiry alongside Indigenous youth and their families, she begins with an inquiry into her lived and told stories of experience of growing up as a child newly immigrated to Canada. Thinking with stories of the youth, she returns at the conclusion of the inquiry to look at the ways her early experiences shaped her understandings of belonging and identity-making (Chung, 2016).

Practical justifications

Narrative inquirers also justify their research practically, that is, by explicitly explaining the possibility of how the inquiry might shift or change one’s practice. As part of the practical justification, the researcher may provide pragmatic reasons for undertaking the narrative inquiry as it relates to their practice. For example, practical justifications are sometimes made in narrative inquiries around questions of ameliorating early career teacher attrition (Schaefer et al., 2014) or in medical education around puzzles concerning the conditions under which medical residents engage in reflecting on their clinical practice (Clandinin and Cave, 2008).

Social justifications

Narrative inquiries must also attend to social justifications in terms of addressing the so-what and who-cares questions important in all research undertakings (Clandinin and Connelly, 2000). Social justifications can be understood in terms of theoretical justification as well as social action and policy justifications. Theoretical justification is understood in terms of new methodological knowledge and/or advancing disciplinary knowledge. The social justification for the research may provoke social actions and/or policy shifts or changes that impact more than the researcher and participant, but also specific demographics, communities, or potentially society as a whole. For example, see studies on early school leavers (Caine et al., 2013b) which offers understandings about the diversity of youth’s experiences of leaving school that lead to changes in school policies and practices, and studies on narrative care (Blix et al., 2020) which offers new concepts for understanding care for elderly and others who need health support.

Touchstones of narrative inquiry

Criteria for judging narrative inquiries follow from the definition of narrative inquiry and the conceptual frame for thinking narratively. To consider the criteria for assessing the quality of a study, narrative inquiries need to be considered with attention to the ontological, methodological, and ethical commitments lived out in a narrative inquiry. Clandinin and Caine (2013) developed a working set of “touchstones” or quality markers, to be used as criteria for assessing narrative inquiries. They draw attention to a touchstone as a quality or example that is used to test excellence or genuineness. Using the metaphor of a hard black rock which may be used to test the quality of gold or silver, the streaks left on the stone by one of these metals is compared with that of a standard alloy. Clandinin and Caine (2013) discussed the critical components of a narrative inquiry and identified twelve kinds of streaks to mark the touchstones.

As Clandinin and Caine developed these touchstones, they turned to the work of other researchers whose work provided exemplars of narrative inquiry as well as to the theoretical roots of narrative inquiry (Caine et al., 2022). The touchstones outlined include:

- A. attentiveness to relational responsibilities, which turns our attention to the need to answer to those with whom we are in relation, to be responsive to others and to the communities of which we are part;
- B. understanding of what it means to engage in the temporal midst, that is, to temporality within, and across, lives, within storied memories, and the making of new memories and with attention to temporality that stretches backwards and forwards;
- C. the centrality of negotiation of relationships at all phases of an inquiry;
- D. the importance of engaging in autobiographical narrative inquiries into who we are, and are becoming, as narrative inquirers. We need to pay close attention to who we are in the inquiry and to understand that we are part of the storied landscapes we are studying;
- E. processes of negotiating entry to the field understood as a co-composed inquiry space between researcher and participant;
- F. attention to the move from field to field texts, and the move from field texts to interim and final research texts;
- G. the need to represent narratives of experience in ways that attend to temporality, sociality, and place;
- H. the place of relational response communities;
 - I. the delineation of personal, practical, social justifications at the beginning and conclusion;
 - J. attentiveness to voices and multiple audiences including participants; and
 - K. commitment to understanding unfolding lives in motion or in the midst.

Relational ethical considerations

Narrative inquirers follow the legal and procedural aspects of ethics outlined by institutional research boards. Ethical considerations are of vital importance because of the relational ontological commitments and thus requires that narrative inquirers undertake research with an understanding of relational ethics. Relationships marked by mutuality, reciprocity, and respect between participants and researchers are central. Clandinin et al. (2018: 198) note that working with relational ethics asks inquirers “to recognize that we live in, and co-create with participants, spaces of uncertainty or liminality, that both defy simply answers to questions of living and simultaneously acknowledge not knowing as part of living ethically in which we, as researchers, take care to position ourselves in places of dis/ease.”

An ethic of care (Noddings, 1984) is a necessary starting point for narrative inquiry, however, narrative inquirers move beyond an ethic of care to relational ethics. While an ethic of care is lived with participants throughout an inquiry, “an ethic of care is not sufficient alone to sustain a narrative inquiry relationship” (Caine et al., 2019:4). Within narrative inquiry, we cannot think with only a personal ethic but must work with a social ethic that allows us to see ourselves as part of larger communities with responsibilities and commitments to more than ourselves and our personal and familial relationships. This move to include both an ethic of care and relational ethics involves a shift to becoming together with responsibility to, and for, each other.

While narrative inquiry is a relational research methodology, it is also “a transaction between people which makes ethical issues and concerns about living well with others central to the inquiry” (Caine et al., 2013a: 580). Therefore, as narrative inquirers live out an ethics of care which directs us “to attend, to listen, and to respond as positively as possible” (Noddings, 2012: 109), narrative inquirers also live out a relational ethics which directs attention to the complex dimensions within research relationships. Caine et al. (2013a) note the ways in which a relational ontology shapes our work with participants’ experiences as we move to issues of representation in research texts. Representations that arise from our relational ontology necessitate “our living with the unfitting story rather than with attempts to tame, sanitize, or analyze. As narrative inquirers we attend to difficult stories and experiences, we stay with them; we dwell alongside potential participants in possible ways to retell them” (581).

The relational aspects compel narrative inquirers to pay attention to particular ethical matters as research texts are written and shared with public audiences. Narrative inquirers understand that a person’s lived and told stories are who they are and who they are becoming and that these stories sustain them. This understanding shapes the necessity of writing research texts that respectfully represent participants’ lived and told stories.

Conclusion

Engaging in narrative inquiries requires careful planning with time to develop and sustain relationships. It requires intentionality, reciprocity, mutual respect, and openness to co-composing inquiry spaces alongside participants. This chapter describes the theoretical foundations of Narrative Inquiry, the processes of thinking narratively, and processes for designing and engaging in an inquiry, and criteria or touchstones for assessing an inquiry. However, the heart of Narrative Inquiry is relational ethics (Clandinin et al., 2018). This relational ethical stance comes with the responsibility and commitment from researchers and participants to co-compose and negotiate spaces within the re/search to retell, relive, and re-imagine new possibilities and ways of living responsibly, individually and collectively, in the world.

Phenomenology is the study of experience as it is concretely lived, a study that works to develop general structures or interpretations from this concrete particularity. Pedagogy, on the other hand, can be delineated through the “pedagogical difference” that separates the experience of the educator from the experience of those being educated. Phenomenology and pedagogy converge not just in their interest in particular experiences on either side of this divide; both imply a position or an “attitude” from which everyday pedagogical experience can be understood.

Phenomenology is a philosophical tradition and an approach to qualitative research that has been adapted to the study of lived experience in fields as diverse as psychology, psychiatry and sociology. In both philosophy and qualitative research, phenomenology is seen as embodying a method with multiple stages or facets, known collectively as the reduction, bracketing or *epoché*. Today phenomenology designates an active and varied international field of research and theory, one that continues to address urgent issues and concerns in education and in a wide variety of other domains.

Edmund Husserl (1859–1938), the founder of phenomenology, conceived of it in explicit opposition to the specialized natural sciences as epitomized in his famous call to “go back to the things themselves” (1900/2001, p. 168). Phenomenology focuses on *subjectivity*, on experience as it unfolds, on the contents of consciousness, rather than on the *objectivity* claimed by scientific experiments or psychological tests and measures. Phenomenology, Husserl writes, describes “objects”—today: phenomena or experiences—as “first constituted as being, what they are for us, and as what they count as for us, in varying forms of ... intention” (1913/2001, p. 275). Our immediate experience of the world is not of an accumulation of indifferent facts and data; it is already “a world of objects with values, a world of goods, a practical world,” a lifeworld (1913/2001, p. 53, emphasis in original). Subject and world are not separated, but are inextricably connected through *intentionality*, the fact that our perceptions, awareness and actions are always directed, are always *about* something. In everyday life, a tree is shade on a hot summer day just as a building doorway can be a refuge on a windy or rainy one. Phenomenology first carefully separates experience as lived from this everyday “aboutness” and asks (for example) about lived objects or experiences themselves (investigating, for example, refuge, exposure, or sheltering trees or doorways).

To understand phenomenology in its pedagogical dimension, it is important to recognize that although the educator and young person are separated by the pedagogical difference, they are united by a relation with particularly pedagogical characteristics and by their immersion in a common lifeworld. Phenomenology, then, can study a child’s book or toy not merely a way to keep them preoccupied or out of trouble—as a busy parent might initially intend. The experience of a book or a toy can instead be revealed as a way of focusing and directing both attention and behavior, structuring the child’s relationship to time, space, and to others around them. A specifically *pedagogical* phenomenology is thus for example able to study childhood risks (e.g. on playgrounds) as something important for their “becoming at home in the world” (Smith, 1998, p. 182; see also Dall’Allba, 2009; Friesen et al., 2012, for further examples).

This chapter begins with brief histories of the development and expansion of phenomenology, both as a philosophy and a research approach in education. It then offers an overview of recent and contemporary variations of phenomenology for research in education and psychology, including a critical evaluation of their deviation from contemporary qualitative validation techniques. It concludes by describing examples of recent developments related to phenomenology and pedagogy.

History: Husserl, Heidegger & Merleau-Ponty

Edmund Husserl conceived of phenomenology very ambitiously. He saw it as nothing less than a new science to rival all others: as a presuppositionless undertaking based on a “pure transcendental ego” that can—through a method that is itself “transcendental”—intuit and describe “pure essences” and develop from them “the most general structure of this pure consciousness” (1913/

2001, pp. xxi, 11). Although such terms and phrases may seem abstruse if not also philosophically problematic, this chapter illustrates that versions of each still play important role in phenomenology today. In his book *Ideas: General Introduction to Pure Phenomenology*, Husserl, like Descartes, takes as his “first consideration” a perceiving self, sitting in a room (Descartes 1637/2006, p. 13; cf. Husserl, 1913/2001, p. 53), reflecting and observing, and extrapolating from this an ideal self (i.e. ego) able to apprehend objects without prejudice or bias. This is a self that is able to fully carry out Husserl’s phenomenological method, the reduction, in its three parts: (1) the “eidetic reduction” which varies the phenomenon in question (in one’s imagination or via concrete examples), comparing and contrasting it in order to establish both what it is and what it is *not*¹; (2) the skeptical *epoché* (also known as *Deskription*), which is the provisional *exclusion* of existing and possible interpretations, theories and explanations to allow the phenomenon appear for what it is; (3) the rejection of the “natural attitude” of everyday purposeful engagement with a relatively impartial, contemplative “phenomenological attitude” (pp. 51–53, 112–114). This three-stage method, Husserl reasons, could theoretically be applied to any given domain of empirical and ideal objects (e.g. concepts) to produce what he called a “regional ontology” (p. 18).

Husserl’s transcendental ego has been widely critiqued. Researchers in phenomenology, like anyone else, are inevitably motivated and fallible. Nonetheless, phenomenological research (like qualitative research in general) has developed ways of compensating for and counteracting these limitations (see below, **Giorgi, van Manen, and contemporary qualitative research: an evaluation** section). Husserl’s versions of the reduction, particularly his notion of *Deskription* remain indispensable in contemporary phenomenology and research. Different methodologists have come up with various ways of understanding and labeling these techniques and their practical implications. Moreover, Husserl’s meticulous analyses of experiences from the first-person perspective still provide valuable insight into “general structures” of experience. For example, Husserl analyzes how the present moment of experience is ordered and “prefigured” through *expectations* based on past experience, and how these expectations can be *broken*:

Expectations [are] ... essentially susceptible to disappointment in all circumstances. Perception brings something new; that is its nature ... [And] it is certainly clear that it is perception that first decides, and that something new can be a slap in the face to all expectation. Think only of prefigured sequences of sensations like melodies.

Husserl (2012, p. 263).

My computer screen, for example, flickers and goes blank, revealing itself—against all expectation—as an inert, perhaps blemished or dusty black surface. Perception or lived experience has ways of surprising us like this and resisting the immediate realization of our intentions. Not only does this ever-present possibility help phenomenology guard against idealizations and solipsisms, Husserl’s notion of the disappointment of expectations forms the cornerstone of the phenomenological account of “learning-as-experience” (see **Pedagogical phenomenology: possible futures** Section, below).

Husserl’s work had an almost immediate international impact, with his insights developed and adapted, sometimes quite boldly, by others, including his own students. Martin Heidegger (1889–1976), the most (in)famous of these, transformed the phenomenology of his teacher in his most influential work, *Being and Time* (1928/1962). Here, Heidegger turns Husserl’s *pure, transcendental* project—focused on *essences*—into an *existential* one—concerned with *being*. Also, unlike Husserl, Heidegger does not begin *Being and Time* by invoking an act of solitary and sedentary contemplation. Instead, Heidegger opens with a critique of Descartes’ rational individualism and with the recognition that we are inescapably “thrown” into both world and time. This “thrownness,” this changing “mode of being,” is what Heidegger refers to as our “being-there” or *Da-sein*. Phenomenology comes into play when aspects of our “being” reveal themselves to us—moments when our own basic conditions come into view or are disclosed in particular ways: “Phenomenology” is thus the analysis of these conditions, of our *Dasein* (*Daseinsanalyse*). It “means to let that which shows itself be seen from itself in the very way in which it shows itself from itself” (Heidegger, 1928/1962, p. 58). The best example of this for Heidegger are moments of crisis where we confront our own death—moments which confirm that our being is time-bound, that being is time, or as Heidegger says “the meaning of *Dasein* is temporality” (p. 380).

Heidegger sees us as engaging with the disclosure of our own being (*Dasein*) through *interpretation*: we work to make sense of, to derive meaning from what we encounter in life. His is thus an *interpretive* or *hermeneutic phenomenology*. Heidegger also develops interpretations, analyses of *Dasein* that help to focus and guide phenomenological research: For example, he shows how we are beings who are *with* others (*Mitsein*) primarily through our common attunement or atmosphere (pp. 172–179). In doing so, he provides a basis for the phenomenological study of lived classroom atmospheres and school climates (e.g. see: Wolf, 2020).

Working from Husserl’s phenomenology and Heidegger’s *Being and Time*, Maurice Merleau-Ponty (1908–1961) developed an existential phenomenology of *embodied* existence. The preface to his *Phenomenology of Perception* (15 pages of required reading for any phenomenological researcher) presents a sympathetic critique of Husserl’s pure ego and his transcendental reduction, and offers this famous characterization of phenomenological “reflection.”

¹Eidetic, meaning “essential,” is taken from the Greek *eidos* (essence). Husserl characterizes phenomenology as a “new eidetic science” (1913/2001, p. 34). More narrowly, the eidetic reduction also refers to what Husserl calls imaginative “free variation” (2012, pp. 354–355), a process which consists of imagining different variations on the (type of) experience being studied.

Reflection does not withdraw from the world toward the unity of consciousness as the foundation of the world; rather, it steps back in order to see transcendences spring forth and it loosens the intentional threads that connect us to the world in order to make them appear; it alone is conscious of the world because it reveals the world as strange and paradoxical ... Perhaps the best formulation of the reduction is the one offered by Husserl's assistant Eugen Fink when he spoke of a "wonder" before the world.

Merleau-Ponty (1945/2012, p. lxxvii).

Merleau-Ponty rejects Husserl's transcendental ego and also notes that "the most important lesson which the reduction teaches us is the impossibility of a complete reduction" (p. lxxvii). Phenomenological engagement for Merleau-Ponty is thus not a retreat from the world, but rather, a matter of experiencing it in a different way. Phenomena are experienced as being released from their common practical or theoretical meanings and are thus allowed to "show themselves" in their relative generality, in ways perhaps strange and wonderful. Embodiment, as both the reference and the mode of our immersion in concrete phenomena, is our "general means of having a world" as well as being, as Merleau-Ponty puts it, an "eminently expressive space" (p. 174). Our "flesh" for Merleau-Ponty is the embodiment of this opposition (i.e. of both having a world and expressing ourselves in it) and of many other oppositions as well: The body sees and is seen; it can be both touching and touched, hearing and heard, sensed and sentient, matter and spirit (1964/1968, pp. 134–144). Merleau-Ponty's work enshrines the body and the space it inhabits in the form of what Heidegger calls an *existentiale*, one of the fundamental dimensions or conditions of our being. In addition to *time* as "the meaning of Dasein," these *existentiale* or conditions also include, as indicated above, our "being with," our *relationality* or Heidegger's *Mitsein*.

"Phenomenology's most important accomplishment," Merleau-Ponty concludes, is that it has "joined an extreme subjectivism with an extreme objectivism." The results of this include a kind of synthesis of objective and subjective that Merleau-Ponty refers to as "intersubjectivity" (2012, p. lxxvi) and "intercorporeity" (1964/1968, p. 141)—experienced conditions in which "perspectives intersect, perceptions confirm each other, and a sense appears ... the sense that shines forth at the intersection of my experiences with those of others ..." (2012, p. lxxiv).

From philosophy to educational research

The story of the adaptation of the phenomenologies of Husserl, Heidegger, and Merleau-Ponty to the domain of pedagogy and education is a long and varied one. It includes, for example, the work of the Dutch Utrecht School of phenomenology in medicine, psychology and human development as well as analyses of the future of education following Heidegger's later conception of the history of *Dasein* (*Daseinsgeschichte*; e.g. Fink, 1959/2022). However, given its brevity, this chapter considers only two exemplary works which explicitly link the phenomenological method together with the study of pedagogical experience. These texts—until recently unavailable in English—provide examples of methods and findings that not only exemplify a specifically "pedagogical phenomenology" but more generally illuminate the path leading from philosophical phenomenology to empirical research.

As early as 1914—while Husserl was still formulating his first philosophy—Aloys Fischer (1880–1937) adapted Husserl's skeptical reduction to constitute a specifically "*deskriptive Pädagogik*" (1914/2021; all quotes from foreign-language sources in this chapter are my own translation.) Fischer begins his text bearing this same title by discussing the difficult relationship of *theory* with everyday pedagogical *practice*: "Theory criticizes practice, wants to improve it, reform it, educate it," Fischer observes (1914/2021, p. 61). This is because "new proposals, criticism itself, are valued more highly than a solid understanding of *what already exists*" (p. 51, emphasis added). In keeping with Husserl's call to "return to the things themselves," Fischer outlines how phenomenology allows research in education to study precisely that which "already exists ... to secure the phenomenon of education as the starting point and guide for [understanding pedagogical] problems" (p. 52). Fischer then explains the bracketing process, Husserl's *Deskription*, in a way that remains instructive for researchers today:

If one wants to describe an actuality to be first investigated as it is, through the phenomenological reduction requiring the renunciation of preconceived interpretations, then it is necessary that one grasps and holds this phenomenon with unwavering fixation, that one lets the individual characteristics become clear and distinct—not even using a name or even a term [as a label]—until the structure of the object, its position to me, its parts and abstract moments, as far as all this is given ... has become transparent (p. 68).

Description, any text where a phenomenon is illustrated or characterized, must be studied in a slow, careful, even painstaking manner—involving multiple re-readings and interpretive efforts. The researcher must pause in order to "dwell with" (Giorgi, 2007, p. 132) this description, to become fixated on the phenomenon of concern and the ways it can be characterized—all while vigilantly refusing to ascribe it any easy label, explanation, or as Fischer says, any "genesis" or "origin" (Fischer, 1914/2021, p. 66). The point is to sustain and vary this examination until the specific phenomenon's aspects, structure, components and moments have become transparent (or today: as transparent as they can be). Fischer illustrates through a very brief but pointed example: An older boy mockingly imitates his father. His father, catching sight of this, shouts angrily: "Stop that!" (Fischer actually describes the father angrily slapping the child. This has been changed to keep the example in the pedagogical [rather than, for example, in the legal] domain.) Such a simple description, Fischer points out, can be interpreted *psychologically*, in terms of the affective dynamics of

the father's anger and the boy's mockery. One can also imagine it interpreted sociologically, in terms of different cultures of parenting (re: the father) and socialization (re: the boy) existing among different social groups.

But it can only be regarded *pedagogically*, Fischer emphasizes, if it is seen in terms of the influence of one party on another. Generally this is the influence of the one who "educates" and the one being educated or "brought up" (p. 58): The father influences the boy, for better or worse, by shouting "Stop that!" Although one's first instinct is likely to judge the father for his angry outburst, this reflex must be avoided at all costs. To simply evaluate a child's and especially an educator's actions as either good or bad is not *Deskription*. Instead, Fischer sees in this phenomenon something (still) widely ignored in educational discourse: This is a "deeper layer" of pedagogical influencing that underlies explicitly deliberate actions. It is influence that is *unintended, accidental, contingent* and *circumstantial*, influence that can never be planned in advance according to certain curricula or theories. Fischer's discovery of this unplannable dimension—which was enabled by refusing psychological and other theories, and by focusing on "the things themselves"—set the stage for further phenomenologically-oriented research of pedagogical phenomena. This includes the first book-length investigation of *Pedagogical Tact: A Study of a Contemporary Form* by [Jacob Muth \(1967/2021\)](#).

Otto Friedrich Bollnow (1903–1991), as a second example, was deeply influenced by Heidegger after attending Heidegger's seminars in the 1930s. Although Bollnow generally did not focus on questions of methodology in discussing the relation of phenomenology and pedagogy, in a talk to teachers given late in his life ([Bollnow, 1989/2022](#)), he outlines a number of descriptive and interpretive "exercises" to direct these teachers' own practical reflections. Like Fischer, Bollnow begins by denouncing the difficulty that so much abstruse and prescriptive theory has presented for teachers. He says he is instead seeking a kind of theory that is very different from technical approaches. Technological understandings of pedagogy, he adds, are developed only to optimize education as what he calls a type of "production." Bollnow's point is instead to develop theory that is *reflective* rather than prescriptive, that does not boldly attempt to *lead* practice, but to more humbly *follow* it. As with Fischer, the uncovering of practice for Bollnow begins with description as a form of "closer 'seeing,'" "a step out of one's usual way of dealing with things" (p. 6).

The next stage in Bollnow's exercises is hermeneutic in nature, involving understanding or interpretation—i.e. the "grasping [of] something as meaningful:"

Understanding is co-original with life itself. But where everything is always-already understood [i.e. in the natural attitude], no interpretation is required. Rather, interpretation becomes necessary only where our usual understanding of life is disrupted by something new, something that does not fit. It is here that reflection becomes necessary.

([Bollnow, 1989/2022](#), p. 5)

Bollnow explains that this sense-making "means: to grasp something initially incomprehensible as a meaningful part of a larger whole" (p. 3). Hermeneutics involves an iterative, circular movement from part to whole, from past to present—from understanding that is only partial to understanding that is ever more (but never fully) complete. Because Bollnow is dealing with specifically *pedagogical* interpretation, he emphasizes that the "whole to which all individual phenomena are to be connected as meaningful is the *human being*; more precisely, it is *the person to be educated*" (pp. 5–6, emphases in original). This insight and the challenge it represents for reflection and interpretation can be seen as tantamount to a specifically "pedagogical" reduction for a particularly *pedagogical* phenomenology. It outlines the interpretive stance to be adopted by the practitioner and also by the researcher once the phenomenon in question has been stripped of theoretical, practical and ethical interpretations and judgments.

What Bollnow sees as emerging from this careful reflection and reduction is a type of "theory" that is not about optimizing educational production, but about the reflective affirmation of the responsibility of the educator to the "whole person" of the student:

This reflection is the origin of educational theory. To put it another way, such theory does not spring from an uninterested "pure" desire to know. It arises from the needs of practice, because the emerging difficulties force the educator to reflect, and to reflect in the original sense of the word [meaning: reflected illumination] ... It develops and expands the horizon in which the educator understands [their] actions[, giving them] a more liberated perspective and greater sense of security in teaching.

([Bollnow, 1989/2022](#), pp. 3–10, emphasis in original)

Contemporary phenomenological methods in education represent ways of taking the results of this type of reflection and giving to them the status of formalized, trustworthy, qualitatively generalizable research findings.

Phenomenology and methodology: Amedeo Giorgi and Max van Manen

In English-speaking academia, particularly in North America, methods for undertaking phenomenological investigations—suitable for proposing, planning and undertaking empirical research—began to be formulated by researchers and methodologists in the 1970s and 80s. These include the "transcendental," "descriptive" and "scientific" phenomenologies of psychologists Clark Moustakas, Paul Colaizzi and Amedeo Giorgi (respectively) as well as the "hermeneutic" phenomenology of educationist Max van Manen.

The last two figures, Giorgi and van Manen, are the focus here. Giorgi's scientific psychological phenomenology exhibits an explicitly Husserlian influence, while van Manen's hermeneutic phenomenology, integrates a range of influences, but sees its ideal in the work of the aforementioned Utrecht School (e.g. van Manen and van Manen, 2021). Giorgi's method is developed in and for psychology; the early articulations of van Manen's phenomenology are explicitly related to pedagogy.

A critical evaluation of both Giorgi's and van Manen's techniques in the light of contemporary qualitative methodology shows their phenomenological methods to be ones whose data gathering is typically interview-based (involving small sample sizes typically half a dozen or more), whose data analysis and method is iterative, emergent and adaptable, whose results are developed recursively and presented thematically, and whose qualitative validity and generalizability rest like perhaps no other method on the researcher's and reader's self-awareness and reflexivity. Investigators adapting either of these methods would begin by asking what a particular kind (or object) of experience is like. In the case of Giorgi's method, this object or phenomenon would be regarded as a psychological one (e.g. jealousy or trauma), for the early van Manen, it would be pedagogical (e.g. teachable moments, caring for troubled youth).

Amadeo Giorgi: "scientific" psychological phenomenology

Amedeo Giorgi (1931-) describes his phenomenological approach—also known as the "descriptive phenomenological method in psychology"—as "follow[ing] Husserl as strictly as possible: it uses intuition, it is descriptive, it acknowledges eidetic findings and it employs the ... reduction along with imaginative variation" (2007, p. 65). Given that Husserl saw himself as developing a new "science" (*Wissenschaft*) in his phenomenology, Giorgi sees his own research method as similarly "scientific" in nature, as producing "factual" and "objective" interpretations or findings (2009, p. 80).² "The researcher begins by obtaining concrete descriptions of experiences from others who have lived through" them, Giorgi explains. Such a sample may involve three or more participants, and the descriptions they provide are seen as being reflective of "the natural attitude" (p. 96). Like other phenomenological research methods, Giorgi's emphasizes that "it is theoretically desirable to have participants remain naive with respect to phenomenological concepts and theories" (p. 99). This means that member checks are generally *not* a recommended technique for increasing accuracy and internal validity for phenomenology. Recorded descriptions are first transcribed and then read by the researcher as a whole. According to Giorgi, references to the first person in these records are to be consequently rendered in the third person. Transcripts are then marked (quasi-arbitrarily) according to "transitions in meaning" to identify individual "meaning units," used as a heuristic for the reductions that follow.

One reduction in particular constitutes "the heart of" Giorgi's "method." It is the "scientific phenomenological reduction" (p. xiv) or what Giorgi calls "description." This refers to

The transformation of participants natural attitude expressions into phenomenologically psychologically sensitive expressions ... The researcher starts interrogating each meaning unit to discover how to express in a more satisfactory way the psychological implications of the lifeworld description (2009, pp. 130–130, emphases in original).

These psychological meanings are gradually developed through successive interpretations and refinements of the data. To bring these meanings into view, Giorgi explains that the researcher must take on a "psychological perspective ... a generic, a-theoretical psychological attitude such as is often assumed by practicing clinicians and therapists every day" (p. 135). "The psychological attitude," Giorgi continues, "focuses ... on how individual human subjects present the world to themselves and how they act on the basis of that presentation" (p. 135)—with special emphasis on feeling, sensing and emotion. Through repeated interpretative reformulations, the researcher gradually develops more general and invariant meanings from the data. Table 1 shows the application of this process to a study of the phenomenon of jealousy, featuring one meaning unit in which Paula, a grade school student, observes

Table 1 The development of invariant meanings from third-person transcript data.

Meaning unit	First transformation	Second transformation
"She can't stand it. Why can't that be her? It is all Paula can do not to cry."	"Paula can barely watch the scene. She wonders why [she] cannot ... be the center of attention. It takes all of her power for Paula not to cry."	"Paula is near despair at that moment, and it takes all of her strength not to cry. She wishes with all her heart that she could be the center of such attention and she tends to emphasize the feeling of loss she feels vis-a-vis the admired one who has it all."

Adapted from Giorgi (2009, p. 164, used with permission).

²Ignoring a vast range of recent developments in the natural sciences—from quantum physics to the replication crisis—Giorgi states that "in the 21st century, advances in scientific knowledge are still pretty much determined by the same criteria as those over the last two centuries" (2007, p. 3). Contrary to Giorgi, then, phenomenology cannot (and should not) claim to be scientific in the same sense(s) that the natural sciences do.

one of her classmates as being the center of attention. Giorgi's scientific phenomenological reduction, perhaps ironically, often involves the *addition* of increasing contextual information to both draw out and heighten the subjective and, in this sense, psychological aspects of the transcribed "meaning unit."

The next step involves reviewing these transformations and working through further adaptations of Husserl's reductions: The researcher must bracket previous knowledge of the phenomenon and also undertake "free imaginative" or eidetic variation:

Free imaginative variation requires that one mentally remove an aspect of the phenomenon that is to be clarified in order to see whether the removal transforms what is presented in an essential way. If the given appears radically different because of the removal of a part, it [the part] is leaning toward being essential (p. 69).

In the case of Paula, the grade school student (Table 1), one could say that there are at least five essential elements: (1) Paula, (2) her feelings of despair in relation to (3) another who is at the center of (4) the admiring attention of (5) peers or others. Arguably, no one of these five elements can be removed without the phenomenon of "jealousy" losing its essential character. For example, if Paula shared in the admiration of others or was herself the center of attention, she would not be jealous; alternatively, if the attention in the scenario were negative, disapproving, Paula's feelings might turn to pity or *schadenfreude*. The phenomenon, as Giorgi puts it, should constitute a structure with neither too many nor too few elements (p. 103).

The ultimate goal of all of this stage is to develop a structure that "comprehend[s] all of the data, even though [it may be] supplied by different individuals [or participants]" as a single whole. In the fifth and final step, this essential structure "is then used to help clarify and interpret [further] the raw data of the research" (2014, p. 6). Analysis of these elements in various configurations, either possible or real, leads Giorgi to insights such as: Jealousy "produce[s] a reduced sense of self in the jealous person. It is as though good things cannot be shared" (p. 165). Or: "The most negative effect of the living of jealousy is actually with the relationship of the experiencer with herself" (p. 164).

Finally, although Giorgi originally developed his method in the field of psychology, he emphasizes that it is ultimately applicable to "any other human or social science The only difference is that one assumes the attitude of the discipline within which one is working: *pedagogical* if it is *pedagogy*, sociological if sociology, etc." (2012, p. 11, emphasis added). It is precisely such a pedagogical disciplinary "attitude" that is outlined by van Manen in his own *early* pedagogical phenomenology.

Max van Manen: hermeneutic pedagogical phenomenology

Throughout his career, van Manen (1942-) has consistently characterized his phenomenological method as a "hermeneutic phenomenology." The overview provided here begins with his most exhaustive articulation of this hermeneutic method, provided in *Phenomenology of Practice* (2014); then, it turns to his earlier discussions of a particularly *pedagogical* phenomenology in *Researching Lived Experience* (1997).

In his book from 2014, van Manen characterizes his approach as an "abstemious reflection" that has as its goal an explicitly foundational "primitive or originary contact with the primal concreteness of lived reality" (pp. 26–41). Following Husserl, van Manen sees this reflection as abstemious or methodical in that it involves the *epoché* or reduction in all of its original three facets. Van Manen introduces myriad methodological constructs to support this careful reflection, including multiple permutations of Husserl's "phenomenological attitude," and of Husserl's eidetic reduction (pp. 215–239).

If the key to Giorgi's method is the iterative and eidetic transformation of "meaning units," then the heart of van Manen's is *writing*. Descriptions and short accounts ("anecdotes" or "examples") for van Manen are first gleaned from interviews and more broadly "from literature and the arts, from life, and from the imagination" (2014, p. 248). These then serve as the basis for the work of "reflective writing" which involves careful and repeated revisions both of the researcher's interpretive texts as well as of the descriptive accounts themselves. According to van Manen, these descriptive accounts can be "heightened" and extended in ways similar to Giorgi's "transformations." In a key passage from *Phenomenology of Practice*, van Manen explains that such imaginative but simultaneously sober writing represents *the* central challenge of the phenomenological research process:

The difficulty of writing has ... to do with two things: First, writing itself is a reflective component of phenomenological method. Phenomenological writing is not just a process of writing up or writing down the results of a research project. To write is to reflect; to write is to research. ... Second ... writing a phenomenological text is a reflective process of attempting to recover and express the ways we experience our life as we live it—and ultimately to be able to act practically in our lives with greater thoughtfulness and tact (p. 20).

Over 15 years earlier, in his 1997 *Researching Lived Experience*, however, van Manen characterizes phenomenology and its goals rather differently: He makes it clear that writing is *not* simply a way to reflect about just *any* given phenomenon. He also emphasizes that phenomenology leads to something more than the expression of "the ways we experience our life." Instead, like Giorgi (2012), the early van Manen insists that to reflect on "a phenomenon always implies a particular interest, station or vantage point in life" (1997, p. 40). Speaking of a specifically *pedagogical* orientation or interest, van Manen adds: "We are not simply being pedagogues here and researchers there—we are researchers oriented to the world in a *pedagogic* way ... aim[ing] for the strongest *pedagogic*

interpretation of a certain phenomenon" (p. 151; emphases added). The early van Manen thus not only emphasizes the importance of a pedagogical stance, he also sees phenomenology as "producing" specifically "pedagogic understandings, interpretations, and formulations" (pp. 151–152). Additionally, van Manen clearly comes down on the *educator's* side of the "pedagogical difference" mentioned in this chapter's opening (see also: Prange, 2005, pp. 58–59). Pedagogical experience, in other words, has characteristics of its own that can be interpreted and analyzed, and this experience (at least for van Manen) is primarily the experience of the educator rather than the one being educated.

Phenomenological writing must not only be oriented to a particular interest or orientation for the early van Manen; its particular *pedagogical* orientation itself must also be "strong," "deep," and "rich." "A strong pedagogic orientation requires that one reads any situation in which an adult finds himself or herself with a child as a pedagogic situation, as an answer to the question of how we should be and act with children" (1997, p. 152). This question of how we should be and act itself represents a kind of "pedagogical reduction" like that identified earlier in Bollnow. The *richness* of this orientation is reflected through vividness and detail; it renders this orientation explicitly generative, capable (as quoted above) of "producing" specifically "pedagogic understandings, interpretations, and formulations" (pp. 151–152). A deep text is one that is ultimately inexhaustible (p. 153). For example, the description provided by Fischer, above, may be seen to display "depth" in its disturbing, layered resonance, while obviously *not* being particularly "rich" in the sense of the "concrete ... thick description" recommended by van Manen (p. 152).

The challenge in taking up a pedagogical perspective, of adopting a specifically pedagogical "attitude," van Manen explains, is that "pedagogy announces itself not as entity, behavior, feeling, or emotion but *through* them" (1997, p. 50, emphasis in original). Pedagogy is available to us through a general *mode*, via a set of *ways* in which we experience the world. It is expressed concretely in terms of the four fundamental dimensions or conditions of our being outlined above: (1) the body; (2) the space our body inhabits and in which it expresses itself (cf. Merleau-Ponty); (3) time (as the meaning of our *Dasein*, cf. Heidegger), and (4) relation which (as Heidegger maintains) can be disclosed through embodied *attunement*.

Van Manen outlines the last of these, the dimension of lived relation, specifically in terms of "the pedagogical relation." This is a special relationship of influence between the adult and the young person, undertaken for the sake of the younger and (ideally) entered into freely by the younger:

The pedagogical relation differs from ... everyday ... relations in that the pedagogue reflectively mobilizes his or her conscious desire and will to give direction and shape to [the pedagogue's] influence. But only when such intentions are responded to by the young person can the pedagogical relation come into existence (1991, pp. 73–74).

Van Manen also suggests that this relation is experienced by the educator or adult in terms of *care*: "I care for this child—for whom this child is and who this child may become" (1991, p. 74).

The tension between caring simultaneously "for whom this child is" and "may become" delineates the central characteristic of the educator's lived *time*: It is divided between the child's or young person's *current* happiness and struggles, and (generally, adult) hopes and plans for their *future*. This tension becomes explicit when educators find themselves saying things like "it's for your own good" or "no pain, no gain." Again taking the side of the educator, van Manen also emphasizes the experience of *hope* in this specifically pedagogical temporality:

the sense of lived time [is experienced] in the modality of hope which I cherish for my child's happiness and becoming. And we experience a sense of lived time in the child's desire to become someone himself or herself, to live for something and to create personal meaning in life (1997, p. 105).

Space and embodiment are ultimately inseparable in pedagogy. Like lived time, they are also marked by a dichotomous tension: As Jacob Muth (in his 1967 study on tact) describes it, this tension exists between "the educative help of the teacher" and "the possible self-help of the child" (2021, p. xx). The task of the educator is thus to carefully negotiate proximity and distance—whether embodied and literal or figurative and metaphorical—and to find "the correct middle point" within it: "to step back whenever possible, but remain available when things turn problematic" (van Manen, 1991, p. 162), to create a "space in which the young person is enabled to make decisions and act in his or her own way" (p. 162).

Experienced pedagogically, time, space, relation and embodiment show that the pedagogical attitude is often experienced precisely in terms of tensions and opposed possibilities: We are asked to intervene in the space between the child's present reality and their future possibility; to give them freedom but often by temporarily limiting their choices. Additionally, balancing the developing individuality of the child with collective expectations—or exposing the child to the world while still protecting them from it—highlight still further balancing acts for the educator. The adult lifeworld of pedagogy is consequently characterized by concern about straying too far on one side or another, as van Manen suggests:

[A]s soon as we gain a lived sense of the pedagogic quality of parenting and teaching, we start to question and doubt ourselves. Pedagogy is this questioning, this doubting. We wonder: Did I do the right thing? Why do some people teach or bring their children up in such a different manner? (1997, p. 147).

In other words, pedagogy is explicitly and inescapably *ethical*. Ethical questions, uncertainties and equivocations are central to its disciplinary, professional and practical perspective. Although a phenomenological inquiry, as noted above, must begin by bracketing precisely the ethical question of “balance” or of “doing the right thing,” questions of right or wrong, of better or worse, nevertheless return. However, in phenomenological inquiry, these questions come into focus only *after* the researcher has engaged in rigorous description or writing, *after* they have bracketed not only ethical judgments, but also theoretical explanations and simple practical solutions. These questions return only *after* engagement in eidetic variation in which the researcher (or practitioner) has explored multiple situations and their variation (e.g. of an educator’s intervention or non-intervention in a specific set of circumstances). Finally, it comes only *after* one has in this way developed a broader awareness of the contingency and complexity of pedagogical action that goes *beyond* any one situation.

As Bollnow puts it, description, reduction and hermeneutic reflection are all means through which “the educator ... develops and expands the horizon in which [he] understands his actions” (Bollnow, 1989/2022, p. 14). By “offering them alternatives,” the work of description, (eidetic) reduction and generalization all allow “educators to take full[er] responsibility for their actions,” Bollnow explains (p. 13). These alternatives provide the opportunity of understanding problems and phenomena not just as they arise in one situation or classroom, but in their broader pedagogical generality. It is in working with examples, in seeing the meaning of varied phenomena coalescing to form the (still ultimately unattainable) “whole” of the child or young person, that one engages with both the challenge and the value of a pedagogical phenomenology.

Bollnow further describes this heightened awareness of both the possibilities and generalities of pedagogy as a kind of “tentative theory” in the service of practice. Husserl before him suggested the term “regional ontology” for a similar type of understanding gained through patient phenomenological investigation. For Husserl and Bollnow, the theory or ontology of the domain in question is one always to be tested and reconsidered in the light of new experience and reflection. As hermeneutic knowledge cycles from present to future, from action to reflection, from pre-understanding to new understanding, it remains forever open to new experience and new insight, meaning that the task of research in pedagogical phenomenology (as for any phenomenology) is always ongoing.

Giorgi, van Manen, and contemporary qualitative research: an evaluation

Despite Giorgi and van Manen’s articulations of not just a method but also of a professional and practical standpoint for their psychology and pedagogy, their respective treatments of the validation of the results of such research remain incomplete. Both tend to look only to philosophical phenomenology for criteria; neither offers ways of validating research results that reflect the language of contemporary qualitative research. Moreover, both repeat Husserl’s error of understanding the potential of their respective methods in positivistic terms of researcher *certainty*. By insisting on the “factual” and “objective” nature of their findings, on “originary contact with the lived reality,” both Giorgi and van Manen (like Moustakas and others) appeal to positivistic certainties to justify their method, much in the same way that Husserl did over 100 years earlier. Such language is likely to introduce difficulties for those defending their research, since it contradicts an established post-positivist or interpretivist consensus in qualitative research. This consensus understands that in any science or methodical investigation (from particle physics through ethnography), all research is based on and can produce only probabilities and qualified findings, not final or objective truths or primal certainties.

Further, if (pedagogical) phenomenology is situated in a post-positivist frame, it can readily adopt common qualitative techniques for maintaining and enhancing validity, reliability and generalizability. Internal validity (or credibility) becomes a question of the quality of the broadly scientific rigor and of writing so valued by Giorgi and van Manen (respectively). It can be judged logically and hermeneutically within the research presentation itself by looking for unacknowledged contradictions, tensions or (in) consistencies in the data or in structures, themes and interpretations. External validity can be evaluated in relation to relevant, related or similar work, whether empirical or philosophical. Both the “phenomenological attitude” and the disciplinary, practical or professional positioning of the researcher in a specifically *pedagogical* phenomenology would also need to be explicitly stated and acknowledged in such research. This could occur in a statement of positionality, and also explored through reflective researcher journaling.

Both van Manen and Giorgi recommend working with others who share the researcher’s phenomenological attitude—if not also their pedagogical and psychological position. Giorgi suggests the involvement of a “critical other” in the process of transforming interview data—one who “should also be able to access the transformations lived through by the primary researcher” (2009, p. 105). Van Manen implies something similar in the form of “collaborative reflection” in a seminar or other small groups (2014, p. 312). Although van Manen and Giorgi do not put it this way, constructive, collaborative feedback on one’s phenomenological text can ultimately contribute to what has been called “naturalistic generalization”—“a reasoned judgment” on the part of informed readers regarding the extent to which findings might apply to other situations (Brinkmann and Kvale, 2009, pp. 260–265). To read another’s phenomenological text is to undertake reflection and research in a way that parallels writing such a text oneself and takes the form of the evaluation of the degree to which themes, structures, and other conclusions “generalize” to the critical reader’s own situation, experience and knowledge.

“Scientific” or “hermeneutic” phenomenological research can also simply be evaluated according to the most general criteria for qualitative research:

Hallmarks of high-quality qualitative research include producing a rich, substantive account with strong evidence for inferences and conclusions and then reporting the lived experiences of those observed and their perspectives on ... reality, while recognizing that these could be multiple and complex and that the researcher is intertwined in the portrayal of this experience.

Cohen and Crabtree (2008, p. 334).

The terms and criteria of qualitative research are much closer to those of phenomenological research than its own methodologists appear to recognize.

Before concluding this section, two additional approaches, designated here as “quasi-phenomenological” should also be mentioned: Jonathan A. Smith’s “Interpretative Phenomenological Analysis” (IPA) and Ference Marton’s “Phenomenography.” Both are psychologically oriented and are arguably based on Husserl’s notion of phenomenology as the study of the “contents of consciousness.” Both focus not so much on direct experience, but on mental constructions and “sense-making,” asking not what a *lived* experience or an *experienced* object is like, but rather about how accumulated experience is viewed, understood or “made sense of.” Together with Flowers and Larkin, Smith defines IPA as “a qualitative research approach committed to the examination of how people make sense of their major life experiences” (2009, p. 1). Phenomenography, on the other hand, is differentiated from phenomenology as follows: “whereas in a phenomenological study the phenomenon per se is investigated, in a phenomenographic study the researcher investigates how (a group of) people *view* or *understand* the phenomenon” (Larsson and Holmström, 2007, p. 62). Phenomenography will ask how a participant “understands” something like the steps in a complex task or a principle from a high school physics textbook. IPA, on the other hand, asks questions, for example, about how “gay men *think* about sex and sexuality” or “how ... HIV impact[s] one’s *sense of self*” (Smith et al., 2009, emphases added). Phenomenology would engage with these matters quite differently—asking after gay men’s concrete experience of sex or sexuality, or, say, about what one undergoes experientially in completing a difficult task.

Pedagogical phenomenology: possible futures

Phenomenological research, like the human phenomena it studies, is unavoidably historical in nature. Pedagogy itself, for example, has not always entailed a holistic focus “on the person to be educated;” nor is it limited today simply to the influence of the older generation on the younger. Populations continue to diversify both inside and outside of the classroom, ensuring that experiential perspectives do indeed become increasingly “multiple and complex,” as Cohen and Crabtree have put it. For example, with the young teaching their elders (e.g. about new technologies) and adults engaged in “life-long” learning, the phenomenological study specifically of the experience of *learning*—not just of the adult educator’s side of the “pedagogical difference”—has become commonplace.

Like the tension-laden lived time, space and relationality of the educator, the investigation of “learning-as-experience” also begins through reference to Husserl, Heidegger and Merleau-Ponty. Moments of learning are understood in terms of the broken expectations and disappointments that Husserl saw as unavoidable in experience: “perception brings something new ... something [which] can be a slap in the face to all expectation” (2012, p. 263). Such moments can move us from un-self-aware “pre-reflective” experience to experience that is *explicitly* reflective, meaning that we become differently aware of ourselves, of others, of what we are experiencing *as such*: “Only in experience, thus turning back on itself, which at the same time is a change in our capacity to experience, lies the actual educative power of experience” (Buck, 1989, p. 3). Experience of this kind arguably unfolds in any learning but is particularly characteristic of the “transformative” learning that occurs through crises and discontinuities (e.g. Mezirow, 1991; English, 2014). An educator’s role in this context is not simply to optimize, to constantly facilitate such learning, but to be sensitized to momentary, individualized manifestations, and to provide the patient support that such reflexive and destabilizing experiences require.

This understanding of “learning-as-experience” is just one example of a kind of broadly pedagogical phenomenology as it continues to expand and develop—both in response to new types of experiences in education, and also to new ideas in the philosophy of phenomenology itself. Over more than 100 years since Husserl’s early philosophy and Fischer’s descriptive method, phenomenology has shown itself to be especially suited to pedagogy in its various permutations, particularly to its intentional and interpersonal emphases and its intrinsic flexibility, generativity and subjectivity.

Introduction

Discourse analysis is an effervescent field, which has undergone a rapid development, as a result of the convergence of influences coming from numerous disciplines: linguistics, anthropology, philosophy, and, more recently, communication, psychology, artificial intelligence. For this reason, the terms *discourse* and *discourse analysis* have different meanings, depending on the field in which they are used (Schiffrin et al., 2001). Recent and current studies reflect the interdisciplinary significance of this field of knowledge, attesting the coexistence of language sciences with the ones in the sociological, psychological, communicational area (Roventă-Frumușani, 2004; Dăncu, 2001; Schiffrin et al., 2001; Jaworski and Coupland, 1999; LeVine and Scollon, 2004). Our perspective on discourse analysis as a research method describes an epistemological framework for investigating discourse as a space of signification, the core of which is represented by linguistics (linguistic pragmatics) and complemented by theories derived from anthropology, sociology, psychology, communication (Suciu, 2005, 2014a,b, 2019).

The concept of *discourse* is shaped along different interpretive tendencies (such as, for example, the restriction to the oral aspect of communication, to face-to-face interaction as the equivalent of the concept of *speech*). From the *Dictionary of Linguistics and of Language Sciences* (1994), we note three uses of discourse, which are also signaled by Baylon (1991): speech, enunciation, rules for chaining the suites of sentences. Since the late 80s, the term *discourse* has incorporated the meaning of “speech in the situation”—in sociolinguistics and sometimes in pragmatics—and that of “text”—used in discourse analysis and in the grammar of the text (Baylon, 1991). From the various definitions attributed to the discourse, three categories have been highlighted where discourse is included: “(1) anything beyond the sentence, (2) language use, and (3) a broader range of social practice that includes non-linguistic and nonspecific instances of language” (Schiffrin et al., 2001: 1).

Since the above framing of discourse reveals its relationship to language, communication, meaning and context, the definition of the field of knowledge that deals with the study of discourse refers to a conceptual association where linguistic, sociological, rhetorical theories are found. Defined as the use of language for social purposes, discourse analysis updates the cohabitation of the epistemological paradigms of pragmatics (the new rhetoric, the theory of enunciation, the theory of language acts) and sociology (ethnomethodology, ethnography of communication, conversation analysis, sociolinguistics) (Schiffrin, 1994). Despite its heterogeneous aspect, discourse analysis finds its unity and consistency in certain points that the disciplines which contribute to its constitution have in common as follows:

- Conceptualization of the discourse as a collective construction;
- Intervention of social and cultural norms, which determine roles and relationships of the participants, as well as the content of the messages;
- Social and interactive character of language;
- Dynamics of the enunciation (Suciu, 2019).

We aim, in this paper, to provide a delimitative description of the discourse analysis, which brings together three perspectives: identifying its peculiarities as a qualitative research, the presentation of its specificity and the relevance of discourse analysis by highlighting its functioning in order to explain the current interaction in several fields. Therefore, in the first part, our approach focuses on defining discourse analysis as a qualitative research by comparison with the quantitative research. Also, the uses of discourse analysis as qualitative research in linguistics, rhetorical criticism, communication, and education are highlighted.

Focusing on the constituent theories and on the concepts used in discourse analysis, we aim to emphasize the role of linguistic analysis in understanding the social. From this perspective we draw attention to relevance of employing discourse analysis in communication sciences, educational settings and in cognitive psychology. Besides, considering discourse analysis as a qualitative

research in other fields, we aim to illustrate how it serves to explain the classroom interaction, so as to discover ways to increase the efficiency of the teaching-learning activity. The examples presented reveal how the discourse analysis helps to describe the interaction in school and to improve communication, the teacher-student relationship: "... insights from discourse analysis in schools can help to make them better." (Temple Adger: 503).

Discourse analysis as a qualitative research approach

Due to its characteristics, discourse analysis is considered a qualitative research approach and it is used in such fields as communication sciences, social psychology, language learning, translation (Schiffrin et al., 2001). Regarding its importance in the study of communication, for example, Tracy has noted: "An upshot of the disciplinary context within which discourse studies emerged is that discourse analysis in communication is conceived as a method of inquiry" (Schiffrin et al., 2001: 726). *The Dictionary of Qualitative Methods in the Human and Social Sciences* (Mucchielli, 2002) incorporates discourse analysis into the category of qualitative research, defined as "discursive and significant approach to reformulate, explain or theorize a testimony, an experience or a phenomenon" (Paillé, in Mucchielli, 2002: 33).

Emerged in the 60s in the Anglo-Saxon space, the term qualitative research designates "a methodological approach that resorts to an interviewing process or to a form of qualitative analysis" (Mucchielli, 2002: 55). Qualitative research establishes a relationship with reality, with the subjects of the research and with the scientific explanation. The roots of qualitative research may be identified in the founding disciplines belonging to the trunk of the social and human sciences, through which they are differentiated from the natural sciences.

The fundamental feature of the qualitative research is the comprehensive (subjectivist/interpretative) perspective, through which human actions are considered phenomena of the meaning. These phenomena can be understood through a specific effort, related both to the human nature of the researcher and to their own nature (through empathy). The interest of a qualitative research is in phenomena (observable events, existential experiences), rather than in the exact, precise language used by an individual in interactions. It provides a reformulation, an interpretation, a theorizing of the phenomena that are lived or observed. According to the qualitative research approach, a text, a discourse, a device, (generally a human creation/achievement) is regarded as a set of collective or individual actions or as intangible phenomena, as representations (e.g., cultural norms, ways of thinking), in order to extract the meaning for oneself and for others. The qualitative approach is not intended to attest a point of view, but to explain it or to argue it theoretically (a reasoned interpretation is proposed to the receiver, more than a proven one). In order to solve a research problem, qualitative approaches comprise mainly ideational operations, that is, techniques of data collection and processing, which are not quantifying, automatic operations. Qualitative researches provide a qualitative analysis of data, through which words are interpreted by means of words, by applying the resources of intelligence to the perception of meanings. The conclusion of this analysis consists of a story or a theory, not of a demonstration (Mucchielli, 2002).

Qualitative research is often presented in comparison with quantitative research. The latter uses quantitative methods of document analysis (generally texts), which are based on mathematical and statistical techniques (sampling, decomposition, numbering, encoding, comparison, linking) and is aimed at discovering the properties of the document. Identifying these properties allows for a commentary on how that document makes sense and creates effects in a particular context. In the qualitative approach, the utilized procedures are based on ideational (reasoning) operations performed on the elements of a document or on a set of documents and have as their objective the explanation of meaning (Mucchielli, 2002). The parallel reveals an opposition that, although considered artificial, is relevant because it emphasizes the distinction between the two epistemological and methodological poles, allowing the identification of the main features of qualitative research (Mucchielli, 2002: 56–57):

- It concerns comprehension, depth (as compared to quantitative research, which seeks control and amplitude and extension);
- The logic of discovery (unlike the quantitative research, which adopts a logic of verification);
- The importance of the context (the context is perceived: it is not posed or considered constant as in quantitative research);
- It is interested in local, circular and symbolic "causality" (as opposed to quantitative research that can establish "causal" relationships and correlations);
- It tries to understand the complexity of situations, in order to present it in detail (while in quantitative research complexity is sublimated or denied).

From a methodological point of view, the qualitative approach involves the use of one or more methods of data collection (e.g., observation, semi-direct interview, group interview, collection of organizational, personal, historical documents, etc., journal, artistic productions, videos, photos, etc.). In collecting data, the researcher is immersive in his/her research, establishes a personal and prolonged contact with the environment, with the people. In order to analyze the data, the investigator may choose among one or more methods (qualitative content analysis by theorizing, needs analysis, conversation analysis, etc.), but his/her involvement is also present at this stage, in that the research tool is represented by his/her own person (while in the natural sciences the instrument is external, for example, the microscope).

The object of discourse analysis, as a method of qualitative analysis is "the enunciative device that correlates a textual organization with a determined social place" (Charaudeau and Maingueneau, 2002: 43). Discourse analysis provides a link between language and social reality in order to explain, through comprehension, a human or social phenomenon. In analytical reflection, the role of context is decisive, primarily due to the integration of linguistic pragmatic theories, namely: the theory of enunciation

(Benveniste), and the theory of language acts (inaugurated by Austin and continued by Searle) and coupled with their interference with Perelman's new rhetoric, the analysis of conversation, and the ethnography of communication. Aiming at clarifying the use of language in concrete situations of communication, "for social, expressive and referential purposes" (Schiffrin, 1994: 339), discourse analysis reveals the functioning and effectiveness of discourse, in other words, the dynamics of interaction.

In discourse analysis, the function of language ceases to be limited to the transfer of information. It acquires the communication dimension, by taking into account the interhuman relationships. The connexion between the protagonists of a verbal exchange is part of the context and is inscribed in the language, a situation conceptualized by the subjectivity of language (Benveniste, 1966). The sender of a discourse uses the words not only with their referential function, of representing reality, but also in order to act on his/her interlocutor, which means changing, modifying an existing state of affairs, behaviors, ideas. Advanced by the pragmatic theory (language is an act), this conception prioritizes the intentional and actional function of language (Suciu, 2005, 2014a,b, 2019), allowing a complex description of social interaction. Participants create and transmit content based on their social role and status, on intention, on the social and cultural norms that work in that particular interaction. The discourse is thus perceived as a collective construction, whose semantic co-construction includes the following elements: the intention of the sender, his/her knowledge of the receiver and of his/her expectations, the socio-cultural framework of the interlocutors, their social context and identity, the relationship between them.

As interdisciplinary field, discourse analysis focuses on the comprehensive aspect, on the study of discursive practices of real communication situations and of the discursive genres generated by them and on the investigation of verbal interaction (Rovența-Frumușani, 2004). Discourse analysis incorporates different orientations—the most important being the theory of speech acts, the interactionist sociolinguistics, the ethnography of communication, the Gricean pragmatic approach, the analysis of conversation, the variationist linguistics—which have a common denominator although they use different research methods (Suciu, 2019). The stakes of this interdisciplinarity concern both the ability to understand the variety of discursive genres in modern and contemporary society and the ability to interact effectively with others, to diminish/annihilate barriers or social/political/cultural disadvantages (Rovența-Frumușani, 2004). Sharing the approach of researchers (Schiffrin, 1994; Rovența-Frumușani, 2004) who treat discourse analysis as an umbrella term, we consider that the analytical perspective proposed by discourse analysis is relevant because it:

- demonstrates how the linguistic fact is responsible for influencing/modifying the social fact;
- supports the role of linguistic analysis as an instrument of understanding the social, the relational fabric established in a concrete plan between individuals and/or groups having the status of social actors;
- reveals the functioning and effectiveness of a discourse and of the dynamics of interaction.

In the light of the above, we consider that discourse analysis is a useful qualitative research method in the study of written or spoken language in relation to the interactions taking place in the social context. The aim of the investigation is to decipher the meanings that escape immediate identification in texts/situations/processes. Depending on the field in which it is used as research method, discourse analysis has various connotations. The use of discourse analysis as a method of investigation in linguistics refers to the examination of a linguistic unit that goes beyond the boundaries of a sentence. In addition, it studies the way in which language is used socially. Discourse analysts in the field of communication are differentiated by the fact that they are concerned about treating the subject in everyday situations. In the field of communication, discourse analysis is the study of speech (or text) in context, where research reports use communication sequences and their analysis as central means of scientific argumentation (Tracy, 2001). The implementation of the method of discourse analysis in education aims to identify the specificity of the language in school, as it is related to the linguistic competence necessary for the student to obtain good results. The interest in the study of verbal exchanges with the help of discourse analysis also goes toward explaining the actions by which learning, as the main target of schools, is achieved (Temple Adger, 2001). In rhetorical criticism, unique political discourses and actions are studied within the theoretical framework offered by literary criticism, political and continental philosophy, history, film studies and so on (Tracy, 2001).

In order to reveal how the pragmatic theory in discourse analysis helps to identify the implicit meaning, we refer to an example that we have discussed on another occasion (Suciu, 2014a,b), leading to the discovery of the sense that is correct and adequate to the context in which it is issued. From the beginning, we should mention that, very often, in communication, the meaning of a message is not always limited to the meaning conferred by the sequence of words and phrases. In other words, the meaning of a message results also/especially from the manner in which it is uttered. The message consists of a sequence of sounds, words, phrases that have a certain meaning, forming the content of the communication or the information. It is accompanied in speech by a specific tone (serious, joking, derisive, etc.), by a mimicry, an attitude or a posture, which complete the literal meaning of the phrases, sometimes even modifying them. All these indicial elements have a role in establishing the register of interpretation of the message (whether it is a joke, a threat, an order, a suggestion, etc.). At the same time, they relate to the knowledge of the type of relationship between the participants in the verbal exchange and have to do with the utterance of the message.

According to the theory of utterance in pragmatics (Benveniste, 1966), the example *This Morning it has snowed* consists of the utterance, which represents the act/activity of a person who uses the language through an individual act of usage and a statement, which is the product of this activity. The statement *This morning it has snowed* is referential (a fact from reality is transposed into a linguistic form), and addressed by a sender to a receiver in a specific context (a certain moment, a certain place, there being a certain relationship between them). We note that the message contains the sender's underlying belief in what he/she says, but it is not expressed explicitly, by using the linguistic features (such as *I affirm, I am convinced*). The conviction, in this example, indicates

the attitude of the sender toward what he/she states and this conviction is contained in the meaning of the utterance, as we will discuss in the next section. If the statement is accompanied, for example, by the linguistic marker *be careful* and/or by the intonation corresponding to a warning, then the correct meaning of the message is one of warning. The message thus carries an indicator of the utterance and thus, it becomes:

This morning it has snowed, therefore you should be careful not to slip/leave home earlier than usual, since the traffic is hampered/put on your hat, etc.

Different features may be attached to the statement either explicitly, verbalized in the statement (*I say, I am convinced, I doubt, I do not think, I hope*, etc.), or non-linguistic and paralinguistic features (gestures, attitude, posture, mimicry, intonation). The indicators of the utterance perform the function of a code by which the statement acquires its complete significance. The precision of its meaning is given by the reference to the data provided by the context. In other words, in order for the receiver to get the exact and correct meaning of the message, he/she will act on the message through reasoning that involves reference to the context, restricting the semantic series of possibilities. For example, depending on the moment when it is issued, the indicator of the statement may be the warning (*you should leave home earlier, the traffic being hampered*), depending on the relationship of the participants, the message may be completed with the urge: *You'd better put on your cap* (if the message is sent by a mother to her child) etc.

Understanding the meaning of a message by using the linguistic features/markers, the paralinguistic features (such as intonation and tone of the voice) or the non-linguistic features (such as gesture) is easier than the case when they are missing (the case of written communication). Assigning a meaning to the message requires the identification of these features in order to deduce the intention of the sender. This purpose is fulfilled by some theories of pragmatics. Although these theories use different concepts, they cover the same object, namely the discursive principles/laws which, by being paired with the context data, help the receiver interpret the message and to reach its meaning.

We consider that, by appealing to theories from pragmatics and rhetoric, to sociological and anthropological theories, discourse analysis approach can provide a complex description and explanation of real life discourse and interaction. Thus, discourse analysis:

- addresses the comprehension of the communication situation in order to explain the meaning;
- goes into deeper layers of analysis, due to the interest in the "local" aspect;
- has the ability to reveal the complexity of situations, explaining them in detail;
- gives importance to the context in interpretation, which reflects the connection with the social aspect;
- determines the understanding of the social aspect, of the relationships established between individuals and/or groups as social actors;
- gives an interpretation that is updated in words;
- demonstrates flexibility and possibility of adaptation to the object of study because the research tool is intrinsic to the researcher;
- contributes to the improvement of the quality of interaction and to the efficiency of communication.

The peculiarities of discourse analysis as discipline of study

The following presentation focuses on highlighting the peculiarities of discourse analysis as a qualitative research, especially the correlation with reality, with the social, through the pragmatic conception that substantiates this field.

A first conception of discourse/communication is related to the customs in Ancient Greece and to the understanding of discourse as an instrument available to the Greek citizen in the form of a pleading. Delivered in public, discourse became a way to defend a personal interest or access a privileged social position. The art of communication (which was called *rhetoric*) developed as a means of persuading the audience, therefore, the interest in acquiring and studying it equaled the magnitude of the interest in the art and science of war, that had already been established at the time. Later, specialists in rhetoric appeared (Corax from Syracuse, Tisias, the Sophists) who developed elements of communication theory, representing communication methods and techniques imposed by practical requirements (to win litigations on wealth recovery, for example).

Plato conceived communication (and, implicitly, the discourse) as a sophisticated process involving not only the study of influencing and persuading techniques but also the study of knowledge, of the meaning of words or of human behavior and ways of life. Unlike Plato, for Aristotle rhetoric was a corpus of technical means to convince the audience and/or win a cause (Florescu, 1973). This definition of discourse implies the social aspect in addition to the communicative intention of the sender, both of them being specific to the pragmatic conception, that is predominant in discourse analysis, as well. Similar to ancient rhetoric, the pragmatic school of thought views discourse as a unit whose identity is shaped not only by its linguistic expression, but also by the assumptions produced by the receiver, relative to the speaker's (direct or underlying) intention and context. One of the points of interference between ancient and pragmatic rhetoric is the communicative intentionality of the speaker (Gross, 2000; Eco, 1996).

Discourse analysis is guided by the inherent junction of the language fact with the social fact, a foundation of the interactional theory which will be presented in what follows. Schiffrein (1994) says that discourse analysis involves six approaches that are considered dominant: the theory of speech acts, pragmatics, ethnomethodology, interactional sociolinguistics, ethnography of

communication, and variational sociolinguistics. The close connection between discourse and society has been supported over time by linguists, sociologists and anthropologists, philosophers, psychologists, mathematicians/computer scientists.

The interactional theory on communication claims the appeal to rules that do not belong to the linguistic code, but to the uses of language, updated in the verbal interaction, without a break from the linguistics of the language/code. Thus, the verbal interaction, viewed in a general way of functioning, is constructed and interpreted with the help of *rules* that are applied in a given contextual *framework*, on a material of heterogeneous semiotic nature (verbal, paraverbal, nonverbal units) (Kerbrat-Orecchioni, 1990). The interactionist theory is the premise for the development of a sociolinguistic research study on communication (ethnomethodology) and of pragmatic theory in linguistics. If the latter focuses on the study of language use, the socio-anthropological approach surveys the role that language plays in relation to society and culture (Suciu, 2019).

Defining language as a “guide to social reality”, in the first half of the 20th century, E. Sapir, updated a sociolinguistic conception of it (Sapir, apud Mounin, 1975: 82–97), of which we point out two significant aspects for discourse analysis. On the one hand, the value of language as a tool that mediates the relationship between the individual and the reality foreshadows the sociolinguistic theories of communication sciences, regarding the effect of communication on the individual and society. On the other hand, the introduction of the social dimension of language, which involves the psycho-social component, is later found in the semiotic and pragmatic theories of linguistics. Thus, the subjective and social stakes of language are converted, in discourse analysis, into issues such as: subjectivity of language, discursive genres and critical analysis of discourse, through the representative research of E. Benveniste, J. Austin, J. Searle, D. Hymes, T. van Dijk (Suciu, 2019).

The sociological perspective has as center of interest the role of language in culture and society and the act of communication as frame of reference. The study of language in its social context, sociolinguistics aims to highlight the relationship between the organization of the message, as a premise of linguistic analysis, and the social implication of this message (Suciu, 2014a). The study of language in sociocultural context branches off into three directions according to the importance of either the social aspect or the linguistic aspect: *the ethnography of communication* (where the social aspect is a priority), *variationist sociolinguistics* (the social aspect is integrated into the linguistic one) and *interactional sociolinguistics* (the social and the linguistic aspects have equal weight).

Pragmatics explain the relationship between the linguistic form and its user (the sender), how language is used in communication. “Usefully defined as the study of how utterances have meaning in situations” (Leech, 1989: 2), pragmatics became a central theory in discourse analysis, which refused to accept the limitation of the meaning in the abstract. Studying the language in situation, (i.e., communication) and aiming at analyzing concrete verbal exchanges as verbal interactions, by referring to participants, use and contexts, pragmatics becomes one of the basic paradigms on which discourse analysis develops alongside with the structural—functional paradigm, the social/socio-linguistic and the critical ones (Baylon, 1991). “Discourse analysis must not only explain why certain statements and not others have been preferred, but also it should account for the way those statements have mobilized forces and influenced social networks” (Maingueneau, 1991: 35). The interactionist perspective in pragmatics is based on three aspects related to language: subjectivity, the implicit and the social, exploited differently in pragmatic theories. The subjectivity of language, being the concern of the stylistic direction, has been reaffirmed by Benveniste (1966), by his theory of utterance (fr.: *l'énonciation*). The theory, from which the *linguistics of utterance* develops is linked to the preoccupation of linguists for the communicative intention of the speaker, named *force meaning* (Thomas, 1995). The utterance indicates how the speaker uses the language in order to work out the intended force and to act on the receiver. Thus, the theory emphasizes the relationship between the speaker and the receiver through their interaction (Suciu, 2005).

The *implicit* is a concept belonging to the cognitive orientation and invested in conversational analysis of H. P. Grice. The *conversational implicature* is defined by Yule (2006) as an additional unstated meaning that the hearer must assume the speaker to convey more than is being said. It deals with the determination of the utterance's meaning and force through the operation of some communication rules (*cooperative principle*) and through the contribution of both, the speaker and the receiver. To the same extent, the implicit meaning serves the speech acts theory (to determine the indirect speech act) outlining the direction of research in analytical philosophy or pragmatics itself, which studies language as an instrument of action. The link between the concept of *discourse* to that of utterance reveals two aspects: the intentionality, to which subjectivity is related, and the implicit, to which the social is correlated (Suciu, 2014a,b). The speaker's intention to produce a reaction in the interlocutor's attitude (*the utterance force*), through the issued discourse entails its conceptualization in the speech act theory. The philosophers of language, J. Austin and J. Searle, conceive language as an instrument of action: the speech act is an action performed by the use of an utterance to communicate (Austin, 1970; Searle, 1972). In the view of M. Pêcheux, discourse analysis offers the opportunity to study the immediate communicative situations through the appeal to the statement—utterance relationship and to the pertinence of the discourse situations, as well as to the possibility to study the social and cultural situations within the pragmatic framework by approaching them with linguistic criteria (Suciu, 2019).

Taking examples from advertising discourse or signature discourse of the organization (Suciu, 2005), we observe that the meaning of the utterance—closely linked to the sentence—indicate the way in which the sender uses the language by an individual act that bears his/her imprint. The funny tone, as a mark contained in the statement, which is explicitly expressed in some advertising messages, imprints the message with a relaxed, familiar atmosphere, thus a reduced social distance between the speaker and the receiver; the sentence will be understood in this orientation of the meaning.

Example: Pringles. Once you pop, you can't stop.

Below, there are two examples of a signature discourse of the organization expressed in a serious, even sober manner (an indicator of the utterance), which make us think about the sender's position of authority (he/she states something being entitled to do so).

Tiriac Bank: *Look ahead!*

Euromedia: *Show up with the best!*

Their interpretation is made on the basis of a common rule according to which a statement that communicate an order or an interrogation implicitly contains the idea of the sender's authority (the sender has the appropriate position to issue an order or to interrogate). The assigned sense of a message is oriented by the explanation of the utterance's meaning, through the intervention of discursive principles in the interpretation realized by the receiver, starting from the literal form of the statement (Ducrot and Schaeffer, 1995). For example, an order/request requires its fulfillment, a question requires for an answer, etc. In conclusion, the receiver's interpretation is based on the discursive principles from the discourse analysis theories and the context data.

Therefore, in order to study the discourse/communication, we consider that the inclusion of pragmatics is profitable for discourse analysis, being supported by the following aspects: (1) the function of some theories favorable to the analysis of a discourse (the interactionist theory, the implicit, the theory of the acts of language); (2) the openness toward the social environment; (3) the inclusion of the argumentative perspective.

Timeliness confronts discourse analysis specialists with a new challenge. The digitalization of communication has instituted new interactive, social and communicational practices, some of them being quantifiable (for example, the frequency of posts). These have not gone unnoticed in what discourse analysis means today. Numerous studies have been devoted to the technical artifact involved in virtual discourse (Baron, 1984; Herring, 2001; Webber, 2001; Kress, 2003; LeVine and Scollon, 2004; Suci, 2014a,b; Suci and Mocofan, 2015; Suci, 2021, 2018, 2019) or digital communication (Walther, 1996; Griffin, 2005; Kasdorf, 2003; Weasenforth, 2006; Frascara, 2012; Duarte, 2008, 2013). In a first stage, concerns about the virtual discourse were directed toward a certain discursive genre, materializing in descriptions of some virtual communication systems, in empirical descriptions of language in online interaction or in studies focused on the variety of discourse in this environment. Subsequently, the interest of research focused on the influence that situational and technical factors exert on communication, generating its variety and complexity (Suci, 2019).

Observations of issues related to the discourse of the digital society, such as the impact of technology on society in terms of users' linguistic or nonlinguistic behavior, interactional and social practices of individuals (users) have led to significant changes in the theoretical framework of approach and interpretation of current discourse. The examination of virtual discourse involves reconsidering the position of the sender (to the text and to the receiver), the receiver (to the text), as well as the inter-relational context in a given communication situation. The technological aspect does not leave its mark on verbal language alone. It is known that a so-called *code*, specific to the electronic environment, exists and operates and, through it, any action taken in this environment (a virtual act such as creating, posting/blogging, activating in a social network, etc.) acquires a meaning (Bădău, 2011).

While reconsidering the discursive approach, discourse analysis confirms its capacity to adapt to the forms of expression that are manifested at present and, at the same time, foreshadows new tendencies in investigation and interpretation. The interdisciplinarity of theories and methods of examination, specific to the field of discourse analysis, in necessary and productive complementarity to environmental factors, is likely to generate an integrated investigative system, which is a generous source for developing strategies for successful creation and interpretation of digital communication (Suci, 2014a).

Relevance of discourse analysis in terms of QUAL research

The role of discourse analysis as a qualitative research in the field of education is demonstrated by several accomplished research projects centered on this subject. It is not uncommon for our scientific preoccupations to be directed toward explaining the linguistic and nonverbal behaviors through which learning, as the main school objective, is achieved. We have focused our attention on the interaction in the academic environment, in order to find ways to make the teaching-learning activity more efficient. We have highlighted discursive strategies able to facilitate learning and lead to a greater efficiency of the teaching process. Since achievement of interaction in the educational institutions is mostly linguistic, we used discourse analysis as research method. Nevertheless, we sometimes considered appropriate to complete this method with elements/notions from the communication sciences, psychology, sociology, education. Here are some of the papers published on this topic: L. Suci, *The Role of Communication in Building the Pedagogical Relationship* (2014b), L. Suci, S., Şimon, *Informing Strategies: building the communication framework* (2015), L. Suci, *In search of a balanced relationship in communication. Discursive strategies that create resonance* (2017); L. Suci, *Practices of interaction between the real and virtual worlds* (2018), L. Suci, M. Mocofan, *Approaches to hate speech in cyberspace. A Metadiscursive Analysis* (2021), L. Suci, *A Look Inside Academic Communication During the Pandemic* (2021).

Usually, the school interaction, based on the transfer of specialized knowledge is characterized by the presence of two types of barriers: the cognitive one and the cultural one. This gap, due to cognitive and cultural barriers, generates an unequal positioning of the interlocutors in the interaction—it is obvious that the teacher, as the holder/possessor of the information, is placed on a higher position compared to the student, whose baggage of knowledge and culture is lower. Their positioning involves relational imbalance and thus interaction is defined by social distance (Meirieu, 2010).

The power of words/communication is a subject that reveals two conceptions which, without excluding each other, are differentiated by placing the emphasis on another aspect that the sending of a statement implies: the fulfillment of the preconditions of the transmission, respectively, its effect. In the view of sociologists (Bourdieu, 1991), the power of communication lies in its

exterior, namely in the achievement of external conditions (regarding status, role, framework, etc.) for a sender/a speaker to be able to communicate (can only work if social conditions external to the linguistic logic of the statement are met). In other words, the sender/the speaker must be legitimate to communicate. Defining the foundations of social power, social psychologists French and Reaven (1959) show that the legitimacy of a sender is based on the understanding on the part of the interaction participants that the sender has the right to demand obedience. Linguistic activity is, from this perspective, one of the various means available to someone to exercise his/her power, depending on his/her social status.

On the other hand, researchers in pragmatics (Austin, 1970; Searle, 1972) consider that the power of communication is linked to the power of words, emphasizing their effect on the receiver. They believe that through words we fulfill an action, they try to prove *how to do things with words*. Based on the concepts of intentionality and action, pragmatics states the fact that in the linguistic expression (in the word) lies the force by which a sender can act on a receiver (Suciu, 2014a,b). Pragmatic theory implies the condition of satisfying the extralinguistic premises of issuance, expressed in the form of the principle of legitimacy (one of the discursive principles). For a statement to be accredited worthy of being believed and thus, followed by effect, it must be expressed by someone in the right to do so, by an authority (Suciu, 2005).

The superior position of the sender, which underlies the principle of legitimacy, refers to the idea of responsibility, seriousness, trust, authority that is entitled to demand obedience and which must therefore be listened to. Sometimes the legitimate status of the sender, which coincides with the declaration of the fulfillment of the upstream of the discourse, is explicitly reflected at the linguistic level of the statement, by inserting some morpho-lexical elements (the relative superlative) or rhetorical ones (antithesis) with the function of arguments of the legitimacy and credibility of the locutor. Omnipotence, special vocation, power become arguments of the sender's legitimacy (Suciu, 2005, 2017).

In school interaction, the teacher enjoys the privileged position in interaction, i.e., the position of authority. This position is based on the legitimacy conferred by the knowledge he/she holds, while the teacher-student relationship is marked by social distance. The teacher's verbal and nonverbal behavior implicitly transmits the meaning of his/her superior position as in these examples: *First document yourself, then we shall talk about it; I know everything, you know nothing!* where the existing social distance is emphasized. In the paper *The Role of Communication in Building the Pedagogical Relationship* we have highlighted some discursive strategies may reduce the distance between the participants and re-balance the pedagogical relationship, for example strategies of indirection (*wouldn't it be better to ..., couldn't you ..., what about ...*), interrogatives strategies (*Do you really think that ...*), impersonal strategies (strategies generating an impersonal message) (*it is adequate to ...*) etc. It is important to emphasize that the implementation of these strategies does not aim at eliminating the social distance, which proves necessary in this type of interaction, the teacher's role being to guide the student in the sphere of knowledge (Suciu, 2014a,b).

In the same register of avoidance to offend the sender (the student, in our case) there are also strategies of positive and negative politeness contained by discourse analysis (Kerbrat-Orecchioni, 1991; Roventă-Frumușani, 2004), for example:

- assertion of a common territory: *Don't you think it's ...*
- explicit formulation of observations attesting the interest, empathy of the sender toward the receiver: *You have to be very tired; You're bored to ..., are you?*
- minimization of criticism, and of the refusal: *I'm a little disappointed with your last work; That's pretty farfetched*
- inclusion of the receiver in the action expressed in the statement: *Let's see your work*

We also emphasize the contribution of the discourse analysis to the investigation of communication through the referential works of Leech (1983, 2006), Brown and Levinson (1987), Kerbrat-Orecchioni (1992, 1994) regarding politeness as a pertinent system of analytical reporting in approaching verbal interaction in various contexts.

Being a face-to-face interaction, verbal behavior, is accompanied by the nonverbal one. Therefore, in order to reduce the teacher-student distance, the contribution of nonverbal strategies is an advantage. In the book *Bridges across the communication* (2017) we analyzed the statement of a specialist in education and of a psychotherapist specialized in human relationships, each addressing a non-specialized audience. I revealed the function performed by mimicry, especially by the language of the eyes, by gestures in creating that particular thread that weaves between the interlocutors in interaction. Contact is established through eye language, attention is mobilized, a proposal for closeness is transmitted. We have found that at the level of the statement, language, style and humor act complementarily, creating a relationship of proximity and familiarity between the sender and the audience, despite the social distance existing in that interaction due to the authority of the sender (the specialist, the expert). These factors are related to the sender's ability to elaborate the discourse by applying linguistic strategies of rapprochement. Also important is the way in which the sender relates to the audience in the transfer of the discourse and the manner in which he/she transmits it.

Timeliness, with the advent of new communication technologies, launches another challenge that the teacher has to face. The study of verbal interaction in the academic environment during the pandemic (2020–2022) highlights aspects related to linguistic and non-linguistic behaviors in the teacher-student interaction carried out online/remotely, such as: replacing the formal framework of communication with the informal one, posting inappropriate photos as the interface at the meeting for the course or seminar on the online platform, low feedback, low interactivity (up to the refusal of interaction), ignoring some explicitly expressed rules regarding the carrying out of activities, neglecting the teacher's moment of interpellation. Trying to explain these behaviors, we have revealed the importance of academic spatial landmarks (the imposing building of the university, the class/seminar room, the hallways, the library with the shelves full of books, the reading room, etc.) in order to set up the common cultural background. The spatial landmarks function as marks/insignia of the place (the university), of the university culture, which compete to the protagonists' sharing of the cultural background, ensuring the transgression of the cultural barrier (Meirieu, 2010) and transmit

meanings that help the student to create a real and correct image of the academic environment. Thus, the student will be ready to assume the appropriate role, updated in the congruence between the discourse and the context (Suciu, 2022).

In conclusion, the affective dimension (understood as regulation of the circulation of affections, cf. Meirieu, 2010), is responsible for the reconfiguration of the discourse with the help of the linguistic and non-linguistic languages that give rise to sympathy strategies. Under these conditions, it is possible to establish the relational balance between the participants in the interaction, which ensures the transmission of information. Without canceling the social distance and the authority of the teacher, the highlighted discursive strategies determine the success of the communication in educational context. The analysis of communication in educational settings attests to the contribution of discourse analysis to the explanation of the interaction in school, to the creation of *a common ground with the student/teacher*, using its insights: pragmatics, anthropology and sociology. The results of this investigation with the help of discourse analysis are relevant in terms of achieving more effective communication between the teacher and the student, with impact on an improved student's performance.

Conclusion

In our approach, we have set out on an incursion into the field of discourse analysis, trying to define it as a qualitative research, by bringing together three angles of approach. First of all, starting from the peculiarities that define a qualitative research method, we have identified them at the level of discourse analysis. This frame of reference outlines the descriptive picture of discourse analysis as a qualitative research approach, by delimiting it from quantitative research. At the same time, by referring to the different uses of discourse analysis in other fields (linguistics, rhetorical criticism, education), we have emphasized that this analytic perspective of discourse study is helping to improve the communication and the activity in school. In order to reveal the meaning in texts/situations/processes, the example discussed reflects the role of the discourse analysis in communication and education.

The detailed presentation on the peculiarities of discourse analysis is intended to complement and support its definition. This perspective highlights the contribution of the theories involved by the discourse analysis (pragmatics, sociological and anthropological theories) to give a description of the discourse and of the dynamics of interaction in everyday reality. Through the examples we have explained the functioning of the discourse analysis in finding the implicit meaning of the discourse.

The relevance of discourse analysis as a qualitative research is addressed by reference to education. The premise is the existence of a cognitive and cultural gap in the teacher-student interaction, coming from the legitimacy of the teacher and the different cultural belonging of the participants in the interaction. In order to demonstrate the possibility of overcoming the cognitive and cultural gap, we have revealed several discursive strategies aimed at reducing the social distance between the participants in the discourse and at rebalancing their relationship. The importance of applying the strategies lies in facilitating verbal exchanges in the educational environment and, therefore, increasing efficiency in the teaching-learning activity. We believe that defining discourse analysis through the three perspectives—which are interconnected and supporting each other—confers individuality to this qualitative research approach that may serve to enhance the effectiveness of communication in several professional contexts.

Introduction and chapter overview

Evaluation research examines whether interventions to change the world work, and if so, how and why. Evaluation can serve both accountability and learning purposes, can help improve programs and inform decision-making about the future of programs and other change interventions. Qualitative evaluations thus serve diverse evaluation purposes. Purpose is the controlling force in determining evaluation use. Decisions about design, data collection, analysis, and reporting all flow from evaluation purpose. Therefore, the first step in an evaluation is clarifying study purpose, intended uses, and intended users. This leads to consideration of how to match qualitative methods to different evaluation purposes and inquiries. Framing qualitative evaluation questions for impact affects fieldwork approaches, units of analysis, and purposeful sample selection.

This chapter begins by reviewing diverse evaluation purposes and the specific qualitative contributions to particular purposes using specific qualitative examples to illustrate key options. The chapter discusses how case studies, interviews, focus groups, site visits, observations, and document analysis can contribute to evaluation. Connecting evaluation questions to intended uses and appropriate methods is a central theme. A variety of qualitative evaluation questions aimed at different types of uses are illustrated with the coronavirus pandemic as the focus. A major issue in qualitative studies is how to select cases and deal with small samples. The answer is to be intentional about choosing among purposeful sampling strategies. The chapter concludes with attention to impact evaluations and inquiry into unanticipated consequences.

The purpose of evaluation

Program evaluation is the systematic collection of information about the activities, characteristics, and outcomes of programs to make judgments about the program, improve program effectiveness and/or inform decisions about future programming. Policies, organizations, and personnel can also be evaluated. Evaluative research, quite broadly, can include any effort to enhance human effectiveness through systematic data-based inquiry. Human beings are engaged in all kinds of initiatives to make the world a better place. These efforts include assessing needs, formulating policies, passing laws, delivering programs, managing people and resources, providing therapy, developing communities, changing organizational culture, educating students, and educating the

general public. In these and other efforts to solve problems, provide services, and make the world a better place, the question of whether the people involved are accomplishing what they want to accomplish arises. When one examines and judges accomplishments and effectiveness, one is engaged in evaluation. When this examination of effectiveness is conducted systematically and empirically through careful data collection and thoughtful analysis, one is engaged in evaluation.

The contribution of qualitative methods to evaluation

Qualitative data for evaluation have traditionally come from three primary sources: (1) in-depth interviews and focus groups with program participants, program staff, and other key informants knowledgeable about the program; (2) program documents; and (3) observations of the program through site visits. In addition, qualitative evaluations are drawing on new data sources like social media, remote satellite scanning, information data bases ("Big Data"), photography and videography, and websites. Qualitative methods are often used in evaluations because they tell the program's story by capturing and communicating the participants' stories. Evaluation case studies have all the elements of a good story. They tell what happened when, to whom, and with what consequences. The purpose of such studies is to gather information and generate findings that are useful. Understanding the program's and participant's stories are useful to the extent that they illuminate the processes and outcomes of the program for those who must make decisions about the program. The primary criterion for judging such evaluations is the extent to which intended users actually use the findings for decision-making and program improvement. The methodological implication of this criterion is that the intended users must value the findings and find them credible. They must be interested in the stories, experiences, and perceptions of program participants beyond simply knowing how many came into the program, how many completed it, and how many did what afterward. Qualitative findings in evaluation illuminate the people behind the numbers and puts faces on the statistics, not to make hearts bleed, though that may occur, but to deepen understanding. That deepened understanding includes the local context where implementation happens to identify the factors and practices that shape implementation and outcomes in different ways. Direct observations allow comparisons of what people say happens in the program with what is actually observed in practice.

Specific examples of qualitative evaluations for educational initiatives will illustrate the contribution of qualitative data to evaluations.

Qualitative evaluation examples

The Technology for Literacy Center was a computer-based adult literacy program that operated out of a storefront facility in a lower-socioeconomic area of a large city. After 3 years of pilot operation, a major funding decision had to be made about whether to continue the program. Anticipating the funding decision, a year earlier local foundations and the public schools supported an evaluation to determine the overall outcomes and cost-effectiveness of the Literacy Center. The evaluation design included both quantitative and qualitative data.

The quantitative testing data showed great variation. The statistics on average achievement gains masked great differences among participants. The report concluded that while standardized testing showed substantial achievement test gains for the treatment group vs. the control group, the more important conclusion concerned the highly individualized nature of student progress. This finding highlights the kind of program where qualitative data are particularly helpful and appropriate. The Technology for Literacy Center had a highly individualized program in which learners proceeded at their own pace based on specific needs and interest. The students come in at very different levels, with a range of goals, participated in widely varying ways, and make very different gains. Average gain scores and average hours of instruction provide a parsimonious overview of aggregate progress, but such statistical data do little to help funders understand what the individual variation means. To get at the meaning of the program for individual participants the evaluation included case studies and qualitative data from interviews (Patton, 2015).

Individual case examples

One case study featured a 65-year-old black grandmother. She worked as a custodian and house cleaner and was proud of never having been on welfare. She was the primary breadwinner for a home with five children spanning three generations, including her oldest daughter's teenage children for whom she had cared since her daughter's unexpected death from hepatitis. During the week she seldom got more than 3 h of sleep each night. At the time of the case study, she had spent 15 months in the program and progressed from not reading at all (second-grade level) to being a regular library user (and testing a grade level higher than where she began). She developed an interest in black history and reported being particularly pleased at being able to read the Bible on her own.

A second contrasting case involved a 42-year-old Caucasian woman who dropped out of school in the tenth grade. She was a clerical office manager. She tested at twelfth-grade level on entry to the program. After 56 h of study over 17 days she received a high school degree making her a high school graduate.

These short excerpts from two contrasting cases illustrate the value of detailed, descriptive data in deepening our understanding of individual variation. Knowing that each woman progressed about one grade level on a standardized reading test is only a small part of a larger, much more complex picture.

Focus groups

To get the perspective of more adult students in the adult literacy program, the evaluator conducted focus group interviews. Students were asked to describe the program's outcomes in personal terms: "What difference has what you are learning made in your lives?" Here are some responses.

- "I love the newspaper now, and actually read it. Yeah, I love to pick up the newspaper now. I used to hate it. Now I love the newspaper."
- "I can follow sewing directions. I make a grocery list now, so I'm a better shopper. I don't forget things."
- "Helps me with my medicine. Now I can read the bottles and the directions! I was afraid to give the kids medicine before because I wasn't sure."
- "Just getting a drivers license was wonderful. I'm 50 years old. I can drive well, but I was scared to death of the written test. But after learning to read in this program, I passed the test."
- I can fill out applications now. You have to know how to fill out an application in this world. It used to be so embarrassing not to be able to fill out applications. At least my application is filled out right, even if I don't get the job, at least my application is filled out right.

These group interview excerpts provide qualitative insights into and perspectives on the individual, personal experiences of adults learning to read. These quotes also illustrate one type of what constitutes qualitative data: direct quotations from interviewees. It is important to note that focus groups generate data through interaction. A common question is when to use individual interviews vs. focus groups. Many evaluations include both. Focus groups are especially valuable for generating data through discussion, prompting conversations so participants can express different points of view and feed off each other to generate additional layers of meaning. But not all topics might be suitable for a focus group, for example, on sensitive topics, topics that might put some participants at risk.

Evaluation through observation

What people say is a major source of qualitative data, whether what they say is obtained verbally through an interview or in written form through document analysis or survey responses. There are limitations, however, to how much can be learned from what people say. To understand fully the complexities of many situations, direct participation in and observation of a program is important. Observational data, especially participant observation, permits the evaluation researcher to understand a program or treatment to an extent not entirely possible using only the insights of others obtained through interviews. Interviews and focus groups will capture perceptions—what people think, feel and say they do—but observations will capture what people do. Of course, not everything can be directly observed or experienced—and participant observation is a highly labor-intensive and, therefore, a relatively expensive research strategy.

The purpose of observational analysis is to describe the setting that was observed and what participants do. This means that observational data must have depth and detail. The data must be descriptive—sufficiently descriptive that a reader can understand what occurred and how it occurred. The observer's notes become the eyes, ears, and perceptual senses for the reader. The descriptions must be factual, accurate, and thorough without being cluttered by irrelevant minutiae and trivia. The basic criterion to apply to a systematic observation is the extent to which the observation permits the reader to enter the situation under study.

For example, an evaluation was conducted of a child development education program for first-time parents. The purpose of the program was to increase the skills, knowledge, and confidence of parents. The program was also aimed at providing a support group for parents. Site visits to the program allowed direct observation of parenting discussions. Descriptions of these sessions then became the primary data of the evaluation. In short, the evaluators were to be the eyes and ears of the legislature and the state program staff, permitting them to understand what was happening in various parent sessions. Descriptive data about the sessions also provided a mirror for the staff who conducted those sessions, a way of looking at what they were doing to see if that was what they wanted to be doing. In addition to direct observations, parents and staff were interviewed.

The purpose of qualitative evaluation

Qualitative inquiry for evaluation is utilization-focused. This means the purpose is to generate results that can be used to make the world, or some part of it, a better place, at least that is the hope and intent. Education evaluations aim to improve educational programs and processes, inform educational decisions, and enhance student outcomes. To be useful, evaluations must be geared to the information and decision-making needs of specific intended users. Evaluations to improve curriculum for teachers are different from evaluations for school board members to allocate funds effectively. The stated purpose of an evaluation expresses the desired evaluation uses and the goals to be achieved. Those who commission evaluations and those intended to use findings determine purpose, which makes determining desired evaluation use and impact a values-based political process. Design decisions flow from purpose. Subsequent decisions about data collection, analysis, and reporting flow from design decisions. Therefore, the first step in an evaluation inquiry process is clarifying desired uses by identifying the study's purpose and primary intended users. Who is the evaluation for? How is it intended to be used? What is the desired impact of the evaluation inquiry?

Different evaluation purposes

Evaluations study the extent to which interventions (programs) work. For interventions to work and be evaluated they must be implemented with high fidelity. To illustrate purpose and impact distinctions, I'll use examples from the coronavirus pandemic that spread throughout the world beginning in January 2020. The pandemic gave rise to many evaluation studies. For example, evaluations examined what affected whether people complied with social distancing advisories. To what extent was protective gear, like masks, used? How did schools, communities, organizations, families, cities, and even countries vary in how they dealt with Covid-19? Why did some people and groups resist vaccinations? What educational approaches and messages were effective in increasing vaccination coverage? Answers to these questions from interviews, observations, and analysis of hospital and school records generated findings that were used to improve programs and determine what approaches were effective and efficient.

Different kinds of evaluation studies serve different purposes.

- Summative evaluations determine if a model or approach works and should therefore be expanded to other places. For example, a summative evaluation of a new curriculum would be used to decide whether to adopt the curriculum for all students and recommend expanding the curriculum to other school districts.
- Formative evaluations aim to improve a policy or program as it is being implemented, for example, when the Coronavirus pandemic hit in 2020 schools and universities had to quickly move their courses online. Qualitative feedback from students and teachers was used to help improve online teaching of existing curriculum books and materials.
- Developmental evaluations provide feedback for generating and trying out new approaches, for example, curriculum had to be developed for online instruction during the pandemic and evaluations helped in that development including what kinds of support and assistance teachers needed who were teaching online for the first time. Programs to support parents in home-schooling had to be developed. Socioeconomic disparities in access to the Internet had to be documented and addressed. Qualitative interviews and observations supported that development. (Formative evaluation aims to improve an existing program or intervention model. Developmental evaluation supports development of innovative new approaches adapted to changed conditions.)
- Action research evaluation aims to understand and solve a specific problem as quickly as possible, for example, shortages of protective gear for hospital workers during the pandemic required adaptations of traditional practices with data from patients, nurses, doctors, and hospital administrators generating lessons that could be shared throughout the world.
- Accountability evaluations judge whether policies have been appropriately followed and whether funds have been properly allocated and used as intended.

No single evaluation can serve all of these different purposes and audiences equally well. With clarity about purpose and primary intended users, the evaluator can go on to make specific design, data-gathering, and analysis decisions to meet the priority purpose and to address the intended audience and users.

Connecting evaluation questions to uses and methods

Utilization-focused evaluation research is meant to distinguish what works from what doesn't work. To get a sense of what this means in real-world practice, [Exhibit 1](#) presents a variety of qualitative evaluation questions aimed at different types of uses illustrated by the coronavirus pandemic as the focus. For each question and intended use, an example of qualitative data is identified.

Impact inquiries involving qualitative fieldwork

Qualitative researchers and evaluators study impact through designs that involve going into the field where interventions (programs, initiatives and policies) are being implemented to find out through observations, interviews, and documents how well the implementation is unfolding and how the people targeted by those interventions are responding. Site visits typically involve a team of researchers and evaluators who spend time at program sites, like schools and universities, interviewing staff and participants, observing operations, and reviewing program documents. Each site visit leads to a report for that site and multiple site visits are synthesized to report aggregate and cumulative program impacts.

Site visits require sensitivity to context and culture. When new cases of polio emerged in a remote area of India, qualitative epidemiologists accompanied the revaccination team and interviewed people in the area to find out how and why some children had missed being vaccinated in the recent campaign. They learned that some Muslim mothers had resisted the vaccination and had hidden their children because they'd heard rumors of a Hindu plot to sterilize their boys. Understanding the resistance to vaccination or other health practices, and developing approaches to overcome that resistance, requires an in-depth understanding of the cultural, social, and political systems within a particular context. Context includes attention to and understanding of important nuances of culture, politics, economy, history, geography, resources, and institutions. Qualitative inquiry makes attention to context a priority both for data collection and for reporting findings. This means documenting diversity and the contextual factors that explain particular variations even while identifying cross-cutting patterns and themes.

Exhibit 1 Illustrative evaluation questions, intended uses, intended users, and qualitative data.

<i>Evaluation question</i>	<i>Intended evaluation use</i>	<i>Intended education users</i>	<i>Qualitative data</i>
1. What are variations in the symptoms of Covid-19?	1. Improve diagnoses and treatment of symptoms.	1. School nurses	1. Observations of symptoms that show up in teachers and students.
2. What are the factors that support wearing masks?	2. Improve compliance with mask-wearing recommendations.	2. Public health educators and advocates of mask-wearing.	2. Interviews with those who comply with mask mandates and those who resist following mask mandates.
3. What are differences in how different cultural, ethnic, racial, and religious communities are affected by Covid-19?	3-a. Target health and education messages to be meaningful and influential to different groups? 3-b. Develop and implement policies to reduce health disparities.	3-a. Leaders and health education workers in different cultural, ethnic, racial, and religious communities. 3-b. Policymakers and political actors.	3.a. Case studies of how different cultural, ethnic, racial, and religious communities react to Covid. 3.b. Interviews with policy makers about how they make public health decisions; case studies of decisions and their effects on different groups.
4. How do school closures affect students, parents, and teachers?	4-a. Improve online education. 4-b. Provide additional services and interventions as needed and appropriate to deal with the effects of Covid-19.	4. Educational leaders, parent groups, student advocates, teacher associations, and family social workers.	4. Focus groups with specific target groups affected by school closures.
5. What are the different policy approaches to the coronavirus pandemic in different communities, organizations, states, and countries?	5. Learn from natural variations in policy approaches to compare and contrast what works and doesn't work under varying conditions?	5. Public health officials in national and international agencies who provide advice about prevention, education, and treatment approaches.	Qualitative case studies of the cultural, societal, political, and economic factors that affect policy differences nationally. Generating lessons from cross-societal qualitative comparisons.

The questions, purposes, and intended users in Exhibit 1 are merely illustrative of the great variety of possible utilization-focused qualitative evaluations that are possible. The key point of Exhibit 1 is to spotlight the relationship between inquiry question, intended uses, intended users, and qualitative methods.

Responses to the coronavirus pandemic have varied greatly by culture, country, and socio-political context. Culturally responsive evaluations position and interpret impacts in the context of cultural understandings.

Unanticipated consequences

People running programs of all kinds establish objectives and implementation strategies aimed at achieving positive impacts. But actual impacts may be quite the opposite of those hoped for and planned. I've evaluated literacy programs aimed at helping high school students learn to read that made them hate reading. I've evaluated juvenile justice programs aimed at rescuing young people from a potential life of crime that propelled them inadvertently on a pathway to becoming hard-core criminals. I've studied interventions that intended to support welfare recipients become economically self-sufficient that contributed to multigenerational poverty. I've seen international agricultural development programs aimed at increasing food production and income from cash crops turn fragile soils into desert through the introduction of inappropriate technological and management schemes. None of these programs were run by uncaring or incompetent people. Quite the contrary. In each case, I found the program leaders and staff to be committed, motivated, hardworking, and deeply engaged in bringing about change but, in the end, ineffective. Indeed, they were not just ineffective but counterproductive, having the opposite of their intended effects.

Qualitative inquiry is especially valuable for identifying unintended consequences and side effects. If all a program evaluator looks at is whether the intended impacts are attained, especially using standard performance indicators such as reading tests, employment statistics, and health outcome data, then other, unintended effects will be missed. To find unanticipated impacts, evaluators have to go into the field where things are happening, observe what is really going on, interview program participants about what they're experiencing, and find out through open inquiry what impacts are occurring, both intended and unintended.

Framing practical qualitative evaluation questions to enhance use

Being practical means that the essential criteria for making design decisions are realistic, contextually responsive, and consequential. Being realistic means asking straightforward questions that generate useful and actionable answers. Being contextually responsive involves understanding the demands, opportunities, and constraints of the situation in which the evaluation will take place including attention to power dynamics. An evaluation that is consequential means that the findings are relevant, significant, and applicable to the purpose intended. This is expressed in utilization-focused evaluation as ensuring intended use by intended users.

A pragmatic qualitative evaluation design is based on six questions:

1. Who are the primary intended users of the findings?
2. What are their intended uses of the findings?
3. To what extent and in what ways can relevant impact questions be adequately answered through qualitative data?
4. Can the design be successfully carried out, taking into consideration such issues as access to information, time available, evaluators' skills, and money or other resources required for the evaluation?
5. To what extent and in what ways will the results be practically useable and useful given the intended purpose of the evaluation?
6. When are findings needed to inform decision-making? (Qualitative evaluations include rapid and real time inquiries, like action research, as well as longer term studies.)

With these questions as context, let's now look at some of the design issues that arise in qualitative evaluations.

Qualitative evaluation units of analysis

A design specifies the unit or units of analysis to be studied. Decisions about what cases to study—issues of both sampling strategies and sample size—depend on prior decisions about the appropriate units of analysis to study. Often individual people like teachers are the unit of analysis, or participants in programs, or students. This means that the primary focus of data collection will be on what is happening to individuals in a setting and how individuals are affected by the setting. Individual case studies and variation across individuals would focus the analysis.

Comparing groups of people in a program or across programs involves a different unit of analysis. One may be interested in comparing demographic groups (males compared with females, whites compared with African-Americans) or programmatic groups (dropouts vs. people who complete the program; people who do well vs. people who do poorly; people who experience group therapy vs. people who experience individual therapy). One or more groups are selected as the unit of analysis when there is some important characteristic that separates people into groups and when that characteristic has important implications for the program. The coronavirus pandemic exposed great disparities in sickness, access to health care, and death by socioeconomic status.

A different unit of analysis involves focusing on different parts of a program. Different classrooms within a school might be studied, making the classroom the unit of analysis. Outpatient and inpatient programs in a medical facility could be studied. The intake part of a program might be studied separately from the service delivery part of a program as separate units of analysis. Entire programs can become the unit of analysis. In state and national programs where there are a number of local sites, the appropriate unit of analysis may be local projects. The analytical focus in such multi-site studies is on variations among project sites more than on variations among individuals within projects.

Different units of analysis are not mutually exclusive. However, each unit of analysis implies a different kind of data collection, a different focus for the analysis of data, and a different level at which statements about findings and conclusions would be made. Neighborhoods can be units of analysis or communities, cities, states, cultures, and even nations in the case of international programs.

One of the strengths of qualitative analysis is looking at program units holistically. This means doing more than aggregating data from individuals to get overall program results. When a program, group, organization, or community is the unit of analysis, qualitative methods involve observations and description focused directly on that unit: the program, organization, or community becomes the case study focus not just the individual people in those settings.

Particular events, occurrences, or incidents may also be the focus of study (unit of analysis). For example, a quality assurance effort in a health or mental health program might focus only on those critical incidents in which a patient fails to receive quality treatment according established standards of quality. A criminal justice evaluation could focus on violent events or instances in which juveniles run away from treatment. A cultural study may focus on celebrations. Specific timepoints could be units of analysis, as the qualitative evaluation could be capturing perceptions and practices at pre-implementation, early implementation and post-implementation stages.

Choosing among all of the possible options for units of analysis and cases for study can become overwhelming, whether the decision is about which time periods to sample, which activities to observe, or which people to interview. The trick is to keep coming back to the criterion of usefulness. What data collected during what time period describing what activities will most likely illuminate the evaluation inquiry? What focus will be most useful given the purpose of the inquiry? There are no perfect qualitative evaluation designs, only more and less useful ones.

The key to making decisions about the appropriate unit of analysis and cases to study is to determine what the evaluation findings will be able to credibly address at the end of the study. Is it useful to have findings about individuals, families, groups, schools, or some other unit of analysis? For scholarly inquiries, disciplinary traditions provide guidance about relevant units of analysis. For evaluations, one has to determine what decision makers and primary intended users really need information about. Do they want findings about the different experiences of individuals in programs or do they want to know about variations in classroom processes at different sites? Or both?

Purposeful sampling for qualitative evaluation

Purposeful sampling involves electing information-rich cases to study, cases that by their nature and substance will illuminate the evaluation question being investigated. The term “purposeful sampling” emphasizes sample selection to serve a particular purpose. Qualitative inquiry typically focuses in depth on relatively small samples, even single cases ($n = 1$), selected for a quite specific purpose. The logic and power of purposeful sampling lies in selecting information-rich cases for study in depth. Information-rich cases are those from which one can learn a great deal about issues of central importance to the purpose of the inquiry, thus the term purposeful sampling. Studying information-rich cases yields insights and in-depth understanding rather than empirical generalizations. For example, if the purpose of an evaluation is to increase the effectiveness of a program in reaching lower-socioeconomic groups, the evaluator may learn a great deal by studying in depth a small number of carefully selected poor families. Purposeful sampling focuses on selecting information-rich cases whose study will illuminate the questions under study.

Purposeful sampling is also called purposive sampling. There is generally no difference in meaning. It’s a matter of which term one prefers. My evaluation and applied research work involves close collaboration with non-researchers (community people) who have told me they found the term “purposive” too academic, off-putting, jargon-ish, and unclear. One said, “Who talks like that?” In contrast, “purposeful” they could understand. It means: for a purpose. No one I knew, including myself, had ever used “purposive” in common conversation. Ordinary people did know, understand, and sometimes used “purposeful.” My aim was to communicate clearly and be use-friendly, so I introduced “purposeful sampling” and ceased using “purposive.”

Case selection is the foundation of qualitative evaluation. The findings from an evaluation will be determined by the cases studied. The type of sample selected should follow from and support inquiry into the evaluation and impact questions being asked. The purpose of a purposeful sample is to focus case selection strategically in alignment with the inquiry’s purpose, primary questions, and data being collected. Here are a few examples of purposeful samples using, again, the coronavirus pandemic to illustrate how the sample is derived from the study’s purpose.

Sampling high-impact cases

High impact cases are studied and documented in depth because of the impacts illuminated and the significance of the case to a field, problem, or society. High impact cases have high visibility. In the United States, the philanthropic foundation *Atlantic Philanthropies* supported a campaign to overturn the juvenile death penalty leading up to the Supreme Court’s 2005 *Roper vs. Simmons* case, which did rule against the death penalty. Given the high visibility and high impact of the campaign, the case study identified critical factors that made the campaign exemplary and examined the question of the likelihood of the Court’s decision having been influenced by the campaign.

A more recent example of a high impact, high visibility case is the story of Columbia University economics professor Jeffrey Sachs, author of the influential and visionary best-selling treatise, *The End of Poverty* (2005). With \$100 million from philanthropic donors, he launched the Millennium Villages Project in 10 African countries with the promise to eliminate poverty in those villages with excellent schools, technical assistance, and low cost innovation in agriculture, health, water, energy, nutrition, and education. The successes and failures that ensued involve case studies of the village projects, but Jeffrey Sachs and his approach constitutes a single high visibility case (Munk, 2013).

In the early days of AIDS research, infections almost always resulted in death. However, a small number of people infected with HIV who did not develop AIDS became crucial outlier cases that provided important insights into directions researchers should take in combating AIDS. Qualitative case studies of these remarkably resilient AIDS survivors provided important insights into the challenges of living with AIDS for those on antiretroviral drugs once they became available. Qualitative studies of community prevention efforts generated life-saving lessons that helped turn back the AIDS epidemic.

Comparison-focused qualitative evaluations

We’ve been looking at the value of in-depth study of significant cases. Now we turn to multiple cases, which intrinsically invite comparisons. Comparison-focused sampling looks in-depth at the significant similarities and differences between cases and the factors that explain those differences. Rigorous qualitative inquiry ensures that evaluation comparisons are systematic and meaningful. Different kinds of comparisons serve different purposes thus, again, the importance of purposeful sampling decisions in design. Given the overall purpose of an impact inquiry, the specific question being investigated, and the data to be collected, what kind of comparative sample would be most appropriate? The next section reviews some major options for comparison-focused sampling.

Outlier sampling

Outlier sampling, also called extreme or deviant case sampling, involves selecting cases that are information-rich because they are unusual or special in some way, such as outstanding successes or notable failures. In statistical terms, extreme case sampling focuses on the endpoints of the bell-shaped curve normal distribution (outliers) that are often ignored (or even dropped) in aggregate data reporting. Schorr (1988) used this strategy in studying especially effective programs for families in poverty, published as the influential book *Within Our Reach*. Malcolm Gladwell’s study of *Outliers* (2008) exemplifies this sampling strategy. He posed the

intriguing question: why do some people succeed, living remarkably productive and impactful lives, while so many more never reach their potential? He did case studies of the lives of hugely successful outliers like Mozart, Bill Gates (founder of Microsoft), and the Beatles. He found that success involves more than intelligence and talent; these outliers benefitted from favorable timing, connections, unusual opportunities, and simple luck.

In evaluation, the logic of extreme case sampling is that lessons may be learned about unusual conditions or extreme outcomes that are relevant to improving more typical programs. In studying an international program with hundreds of local sites around the world, we can expect that many local programs are operating reasonably well, even quite well, and that other programs are having difficulties. We also know that most programs average in performance. This information comes from knowledgeable sources who have made site visits to enough programs to have a basic idea about what the variation is. With limited time and resources an evaluator might study one or more examples of really poor programs and one or more examples of really excellent programs. The evaluation focuses on understanding under what conditions programs get into trouble and under what conditions programs exemplify excellence.

Brinkerhoff's (2003) *Success Case Method* for program evaluation provides a systematic way to identify successful programs, compare them to less effective programs, and figure out what makes the difference. In a single program the same strategy may apply. Instead of studying some representative sample of people in the setting, the evaluator may focus on studying and understanding selected cases of special interest, for example, dropouts vs. outstanding successes. In an evaluation of the Caribbean Agricultural Extension Project we did case studies of the "outstanding extension agent" selected by peers in each of eight Caribbean countries to help the program develop curriculum and standards for improving extension practice. The sample was purposefully "biased," not to make the program look good, but rather to learn from those who were exemplars of good practice.

In essence, the logic of outlier sampling is that extreme cases may be information-rich cases precisely because, by being unusual, they can illuminate both the unusual and the typical. In proposing an outlier sample, as in all purposeful sampling designs, the researcher has an obligation to present the rationale and expected benefits of this strategy as well as to note its weakness (limited generalizability).

Positive deviance

Positive deviance is a special application of outlier sampling that focuses on finding people or communities that have solved a problem where the norm in the area is for the problem to remain unsolved. This approach emerged in the 1970s in nutrition when researchers discovered that some families in poverty had well-nourished children. The thing that distinguishes positive deviance from more general outlier sampling is that the search for positive deviants is specifically aimed at finding high impact solutions, it is action-oriented. (Pant and Odame, 2009; Pascale et al., 2010). Advocates and practitioners have formed the Positive Deviance Alliance to promote using this method. Here's an example.

Typical case sampling

This strategy involves selecting and studying several cases that are average to understand, illustrate, and highlight what is typical and normal. Sometimes an evaluation will focus on outliers, but sometimes the focus is on typical students. For example, in describing a culture, community, or program to people not familiar with the setting studied it can be helpful to provide a qualitative profile of "typical" cases. These cases are selected using statistical data about what is average, or with the cooperation of key informants, such as program staff or knowledgeable community members, who can help identify who and what are typical. Keep in mind that the purpose of a qualitative profile of one or more typical cases is to describe and illustrate what is typical to those unfamiliar with the setting—not to make generalized statements about the experiences of all participants. The sample is illustrative not definitive.

When entire programs, schools, universities, or communities are the unit of analysis, the processes and effects described for the typical program may be used to provide a frame of reference for case studies of "poor" or "excellent" sites. When the typical site sampling strategy is used, the site is specifically selected because it is not in any major way atypical, extreme, deviant, or intensely unusual. This strategy is often appropriate in sampling villages for community development studies in low-income countries. A study of a typical village illuminates key issues like school access for girls that must be considered in any development project aimed at that kind of village.

In summary, there are many purposeful sampling options. In evaluation and policy research, the interests and information needs of decision makers and intended users of the findings will shape the sampling strategy.

Key informants, key knowledgeable, and reputational sampling

Key informants are a prized group. These are people who are especially knowledgeable about a topic and are willing to share their knowledge. Key informant interviews were developed by ethnographers to help understand cultures other than their own. Because being an "informant" can have negative connotations, I prefer the term key knowledgeable. They inform our inquiry when we tap into their knowledge, experience, and expertise. Key informants are especially important sources on specialized issues. The evaluation of the implementation of the Paris Declaration Principles on development aid relied heavily on key informants in

governments and international agencies because the topic is highly specialized. A study of New Zealand's Prostitution Reform Act identified and interviewed as key informants "those who have had direct experience of working with or as sex workers".

Key knowledgeable may stand alone as a purposeful sampling strategy or be used in combination with other approaches. For example, identifying outliers or typical cases may begin with key informant interviews. Key knowledgeable provide valuable expertise on and insights into the root of problems, as in a study of barriers philanthropic foundations experience that limit their capacity to think and act strategically. Key informant interviews are widely used to identify trends and future directions as when Gopalakrishnan et al. (2013) interviewed more than a dozen foundation leaders, evaluation practitioners, and social sector thought leaders to identify "Next Generation Evaluation" characteristics and approaches. In essence, key knowledgeable interviews are among.

Utilization-focused qualitative evaluations

Utilization-focused evaluation is an approach to evaluation aimed at intended use by intended users (Patton, 2008, 2012). Within that overall framework, utilization-focused sampling involves selecting cases that will be relevant to the issues and decisions of concern to an identifiable group of stakeholders and intended users. Such sampling can employ any purposeful strategy but adds a requirement that cases selected for study will have credibility, relevance, and utility for primary intended users. The ideal way to meet these criteria is to actively engage primary intended users in design and methods decisions, especially sampling. Focusing on generating useful and actionable findings, a common result of utilization-focused qualitative inquiry is identification of factors that explain the differences between what works and what doesn't work. Those factors and explanations can be used to inform decision-making and support program, practice, and/or policy improvements. To accomplish this action-oriented result, cases must be selected with that kind of finding and use in mind. This means attending not only to the relevance, contextual diversity, and complexity, but having sufficient access to in-depth information about the cases to be able to decipher individual case dynamics and cross-case patterns that will support conclusions about causal factors and recommendations about actions to be taken more generally beyond the cases studied. That increases impact.

Having weighed the options and considered the alternatives, evaluators and primary stakeholders make their design and sampling decisions, sometimes painfully, but always with the recognition that there are no perfect designs. The sampling strategy must be selected to fit the purpose of the study, the resources available, the questions being asked, and the constraints being faced. This holds true for sampling strategy as well as sample size.

Conclusion

Which qualitative evaluation design is best? Which qualitative evaluation strategy will provide the most useful information to decision makers? No simple and universal answer to these questions is possible. The answer in each case will depend on the purpose of the study, the scholarly or evaluation audience for the study (what intended users want to know), the funds available, the political, organizational, and cultural context, the interests/abilities/perspectives of the researchers, and the intended impacts sought. The word "design" is both a noun and a verb, denoting both the product and the process of planning an impact-driven inquiry. Issues of context, resources, purpose, and hoped-for impact all come into play as the design emerges and is then implemented and the results used.

Introduction: a photograph

A young woman is sitting in long summer grass. She wears a floral dress and a Covid-dictated mask in matching fabric. A mirror in an ornate wooden frame stands—serendipitously—against a nearby tree. She reaches out to touch her image in the mirror—a girl who, although her mirror reflection, has nothing covering her face (Fig. 1).

The photograph is one of a series in an online exhibition in the 2020 INSEA conference. The artist, Michaela Petřek Linhartová, plays with images of mask wearers—some humorous, some fantastical, some macabre, and all somewhat unsettling—to explore practical and psychological effects of the first months of Covid lock-down.

It is possible to look at this photograph in a number of different ways. We might simply delight in the doubling of the masked and unmasked figure. We might delve into how the deceptive mirror image was created. We might focus on the incongruity in the semiotics—restrictive mask and the pretty girl, floral dress and burgeoning summer landscape. We might toss around *meanings* of the work, speculating about how the maskless mirror image reflects the yearning in the soul of the masked girl. We might consider the work as one item in the artist's deliberate inquiry into the impact of Covid on individuals in her community. We might see it and the rest of the series as direct evidence of the national mandated isolation that forced the artist to work within a context of tightly restricted contact and movement. And perhaps we might see other things.

This range of possibilities highlights the interconnections between art and research and the potential and challenges in arts-based research, and so points to my intentions in this chapter. I am interested in the fluidly morphing continuum that connects art and research, and in the ways arts and research play with elements of that continuum. I am also interested in the ways that the use of arts in research open up further possibilities in the broad and already varied field of qualitative research.

Fig. 1 Image in the mirror.

Qualitative research focuses on the particular, detailed and contextually situated. It acknowledges and even celebrates the partial nature of each contribution to knowledge, arguing the usefulness of discovering and responding to the specifics of people's experiences, understandings and interactions. It utilizes a wide range of tools and in recent decades processes of arts have become significant items in its repertoire. I explore how some researchers have used those tools.

There is already a substantive and growing body of writing about arts-based research (including Barone and Eisner, 2011; Leavy, 2017) and I have contributed to it (Greenwood, 2012, 2016, 2019). This writing will not offer a summary of or a commentary on that considerable array of writing although it will lightly reference some of it. Rather it focuses on the investigative elements that are inherent in the arts and, drawing on examples from my own work and that of my doctoral students as well as the published work of well-known practitioners, it examines a range of ways the research potential of art had been used in specific research projects. It discusses how art-based research interacts with research, art and knowledge.

A word about terminology. I need to emphasize that although arts-based research is a useful umbrella term there is no one arts-based methodology. I will use *arts-based* research to signify the umbrella term. When I refer to a specific process I will talk about an *art-based* approach. And because it is the domain I work with I would like to clarify drama/theater terminology. Theater is the parent art: as Schechner (1988) explains, it takes many forms and serves many functions. *Drama* is the term used by many British and Scandinavian practitioners to describe the use of facilitated theater strategies as processes for exploring situations and as a media for learning. Other Europeans and Latin Americans tend to prefer the term *theater* to cover this kind of work. Applied theater and process drama are terms that are also commonly used. When citing others' work I will use whatever term they used; in talking more generally I will use *drama* when I talk about specific applied investigative or learning strategies and *theater* when I talk about the wider art domain.

In this chapter I first explore ways research is embedded in the making of art and ways some artists have deliberately used their art to question and provoke investigation. Next I situate arts-based research within the broad qualitative paradigm. I then report some more formally academic uses of art in research and consider how these examples prompt further questioning of the nature and purpose of research and its relationship with learning. I suggest that while a broad range of both popularly accessible and professional arts may be used in research, certain elements are essential. Finally I highlight contributions arts-based research can make to our ways of knowing. First I acknowledge my own positionality in the discussion.

My positionality

Later in this discussion I will argue that an art-based approach to research is unlikely to be dispassionate and further that the subjectivities that come with arts-based research are themselves purposeful and interesting. Therefore it is useful to explain some of my own practice in the arts and research. I am a writer with particular interest in theater. I also work extensively using various drama/theater strategies for teaching and learning. As an academic researcher I use a wide spectrum of approaches. Almost all are qualitative; some are explicitly arts-based, others include historical and current case study, participatory action research and narrative inquiry. Looking back over my work I see vestiges of my interest in theater in all my research: I am particularly interested in and attentive to the people involved and their shifting perspectives, the impact of place, the unfolding of action, and the tensions that are played out. As a doctoral supervisor I have worked with emergent researchers from a many different countries and cultures, and again I find that my drama/theater practice urges me to consider the tensions they may face in navigating western academic expectations and what is meaningful and useful in their local and cultural context. My own experience makes me reluctant to draw too definite a line between art and research and even between arts-based research and that of other kinds.

My husband, Gerry, has been a visual artist who throughout his life explored wood, clay, bronze, pencil and paint. For many years he was a full-time potter producing both domestic ware and more sculptural pieces. As I lived alongside his processes of making I became very aware of the constant exploration of materials and of understandings of the world that impelled his work. I recognize that for him art was a persistent process of research.

Researching through and in art

Research through art has a much longer history than the popularization of the term arts-based research. Artists, it may be argued, seek to know the world through their making of art, and seek to offer others new insights into the world through what they present in their art. Novelists like Proust, Joyce and Woolf explore the phenomenon of time and its impact on human awareness and understanding. Perhaps their own intuitions and their strategies of inquiry evolve as they write. They are researching both *what* they write about and *how* they can write about it with authenticity. They offer their readers new knowledge: disturbing their existing schema about the nature of reality, provoking new insights and new questions.

Painters like Monet, van Gogh and Picasso probe the relationship between what their eyes see and what they experience because of their seeing. They also probe the ways they can manipulate paint to capture and communicate their exploration.

In his *Antigone* the dramatist Anouilh uses the lens of a well-known play by Sophocles to critically analyze and problematize moral dilemmas of resistance in occupied France. The epidemic transformation of ordinary intelligent citizens into short-sighted, thick-skinned and savage rhinoceros in Ionesco's play, *Rhinocéros*, serves as a critical lens to probe the collective hysteria

of people who not only readily accept the dictatorship of fascism but also willingly surrender their judgment and their moral accountability (Ionesco, 1960).

The artists mentioned above can readily be seen as deliberately using their art to probe the human condition and provoke conceptual reconsiderations. But art making is itself a form of research. Artists explore their materials and the possibilities of their interaction with them.

Each time he centers lumped clay on the wheel and teases it to open and flare out into the curve of a bowl or bottle, a potter is engaging in an inquiry into that piece of clay and into the impact of the movement and pressure of his hands. As he fires the kiln and builds the fire he is intensely engaging in experimentation—new for each firing because of weather outside and the placement of pieces inside—with how to spread and intensify the heat, how to reach 1300 °C uniformly through his kiln, how to ensure the oxygen is reduced sufficiently so that his black glazes gloss and break into red, and his whites pool in milky thickness and thin to flash shimmers of color.

So too the actor hunts for the physicality and the verbal nuances that will meld together the character, her own bodily reality and the evolving collective cast understandings of the intentions of the play. The writer fights through a jungle of possible words, tracking elusive ideas, resisting hijack by runaway familiar discourses, shifting blocks of development across pages, hunting for those words that have the right edge of meaning.

Making art, it can be asserted, is a continuous process of research.

Arts-based qualitative research

Broadly speaking, qualitative research enables us to understand and prompts us to interpret the human impact of situations and events. As I make the final edits to this chapter, the invasion of Ukraine has passed its hundredth day. Each day the media publishes positional maps and numerical data. This quantification allows us to appreciate the magnitude and the shifting parameters of the combat and of its effects. For the numbers to have meaning in terms of actual people and their lives, we need to know more: we need to know about the experiences of individuals and about the complexity of the social dynamics of the particular localized contexts in which people strive to make sense of their experiences. And we need to be offered lenses for interpreting these matters.

This is the role of qualitative research, an umbrella term for an increasing array of investigative methods that examine the situatedness and complexity of particular aspects of an issue. It also provides conceptual lenses that offer the ability to make critical interpretations of events and people and to frame the significance in particular ways (Denzin and Lincoln, 2018). Arts-based qualitative research offers the use of an art medium as a means of capturing situated instances of such complexity. The making of art allows probing, and often openly subjective, interpretation. As an example, in the war on Ukraine, personal stories of children who were eventually evacuated from Mariupol and photographs of the tense faces of firemen straddling burned out rafters in a bombed apartment-block humanize the statistics. At the same time, they offer the investigator's interpretation and also invite the audience's critical reaction. The examples that follow illustrate in more detail the possibilities of arts-based qualitative research further.

Expanding existing forms of art to facilitate research

There are artists who deliberately shape their art forms to engage others in investigation and analysis. I offer examples from the field with which I am most familiar. One such artist is Boal, a theater practitioner whose work has cut a path from stage-centered activist performance through a progression of theater forms for collective investigation and problem-solving to the creation of a community-groups-centered legislative theater. His early theater was shaped by a commitment to engage with social issues: in the context of a dictatorship in Brazil his theater company's project was to make art a means to fight for national liberation. Over time he developed what he later called the *Theater of the Oppressed* (Boal, 1979). His intention was to create forms of theater where audiences could become active in examining the oppressions they experience, communicate with each other to analyze the context and causes and to explore possible solutions. Central to the work were facilitator-led processes for keeping the focus *real*.

For example, *Image Theater* is a physical enactment process for groups to select an experienced oppression for examination, identify the power relation between oppressor and oppressed, brainstorm and critique ideal outcomes, conceptualize how the power imbalance might be shifted so that a positive outcome would be possible, and decide on a first step in a direction leading to a shift in power. The facilitator reminds participants that they cannot call on *magic*, that the only initiatives they can propose are ones they themselves can take and not those they may hope for from the oppressor. The first step has to be a practical one that can be taken in the current circumstances (Boal, 1979). Boal's process shares features with academic research strategies like participatory action research in that it has an evolutionary exploratory design and actively involves participants in defining the object of investigation and in carrying out the investigation. In discussing participatory action research as a social practice Kemmis and McTaggart (2005) highlight the importance of first developing communicative space that enables communicative action and consequently an exploratory space that supports exploratory action. Boal's process provides such spaces in which participants can communicate and explore through physicalization as well as in words.

Later in his life Boal entered formal politics and was a city councilor in Rio de Janeiro. He adapted his theater processes to a means of political engagement with his constituent communities. Very simply, his office staff involved a team of actors who would

engage theatrically with disadvantaged communities to select and explore social problems they wanted resolved and, following a performance in which they could intervene to change the course of action, vote on legislative changes that Boal would then bring to the City Council (Boal, 1998).

Two guiding beliefs are evident in Boal's approach. One is the value of collaborative inquiry. "The solution has to be discovered together," he says. "We bring a true question so that everyone can freely and democratically participate and intervene." (Boal, 1996, p. 25). The other is the power of the creative curiosity latent in all people. "We begin from the principle we are all artists, but handicapped artists because education handicaps us." He adds, "We are theater ... By observing myself in action, this dichotomization allows me to change my way" (Boal, 1996, pp. 34–35). His words assert that collaborative engagement in the creativity of art-making opens up and intensifies a common human capacity to critically investigate and to problem-solve.

Independently from Boal's work Heathcote also developed a project of using theater strategies, for which she preferred the term *drama*, for participant inquiry into social and ethical issues. Her use of teacher-in-role and the alternation of frames of action with deliberative reflection created an educational movement which is variously called *process drama*, *applied theater* and *drama as a learning medium*, and which has been copied and/or has been modified and adapted by numerous well-known theorizing practitioners (including O'Neill, 1995; O'Toole, 1992; Taylor, 2003; Schonmann, 2011) as well as by classroom teachers. While this form of work is designed to be investigative and analytical, its initial primary objective is a vitalization of teaching and learning process rather than research. However, the evolution of methodologies such as action research and reflective practice problematizes demarcation between learning and research. Much of the work carried out in arts-based research fits into a nexus between learning and research.

In New Zealand in the 1970s Wilson, a Māori sculptor and educator, developed a project, lasting almost two decades, that used art-making as a catalyst to challenge and change the monocultural bias of schooling (Greenwood and Wilson, 2006). Participating schools, represented by about twenty students and three or four teachers, would be brought to live for a week in a Māori space and work with the local Māori elders, artists and community to develop a mural, and sometimes other art forms, depicting a local story of place. To research their story and the traditional art forms for their mural the groups would need to learn from the local holders of knowledge. In this context research took an experiential form: the participants lived immersed in a space where Māori values and protocols were normal, listened to elders talk, helped in the kitchen, worked communally with artists who were expert exponents of their traditional forms. What was explored reached beyond the selected story and means of accomplishing the art work: it involved lived experience of different values and ways of seeing the world, and sometimes a revaluation of participants' own identity and societal role. To call such investigation research somewhat stretches commonly used definitions: the process was variable, and, while there was expectation of broad outcomes, the deeper discoveries were made at personal and small group levels and were neither predictable nor measurable. Much of the new knowledge would have been hard to put into words as it involved affect as much as cognition. The project invites reflection on the nature of research and the forms, popular and academic, that it might take, and about the kinds of knowledge research in and through the arts might generate.

Art teachers researching academically

In terms of how art forms are used there is a strong relationship between projects such as those of Boal and Wilson and those that formally construct themselves as academic research. The key difference perhaps is in terms of nominated focus, explicit, albeit sometimes evolving, methodological procedure and explicitly discussed outcomes. These factors are illustrated in the work of two post-graduate students.

Trudy Barrett's project (Barrett, 2014) took place in a secondary school art classroom where she needed to work within the prescribed curriculum but was given freedom to find her own approaches. She developed a progression of activities that each taught a particular skill and at the same time provoked students to incrementally examine and enrich their understandings of themselves and their situatedness. Barrett began with an explicit research question: "How can visual arts teachers use art making to help adolescent students to recognize, critically analyze, and interpret their senses of self, place, and community?" (p. 26). She details her methodological design and explains how she will collect and analyze her data and present her findings. She is explicit in identifying the historical, philosophical and epistemological contexts in which she has situated her study. She explains how she navigates the methodological duality of her work: the teaching methodology that is intended to provoke student inquiry and the research methodology that allows her to critically reflect on and evaluate the effect of her teaching and the visible and verbalized shifts in students' conceptualizations. She reports her findings verbally and in images of the artifacts.

Barrett's study engages with both verbally analytical interpretation and the less definable esthetic dimensions of her and her students' work. Montages of photographed artifacts complement her narrative, as does a series of manipulated images through which she reflected on the relationality of her role as insider and outsider, as teacher, researcher and artist, as a woman with her own history. She remains artist throughout her investigative journey at the same time as she adheres to the rigors of academic research. She offers us a basis on which we can critically discuss her findings, and the same time she lures us to further play with the presented images and accounts and explore their esthetic reverberations.

While it is generally agreed that an esthetic dimension is an intrinsic element of art, there is less agreement about what constitutes the esthetic. Minimally it can be described as an element that affects the senses and triggers subconscious responses as well as rational ones: it speaks of a dynamic interaction between art and viewer; perceptions vary historically, culturally and individually (Greenwood, 2010).

As a primary school teacher Toby Greenwood wanted to explore esthetic responses of 10–12 year old students (Greenwood, 2011). He explains that his own research question was: “How do students formulate and express their esthetic response to their own work and to that done by others?” which he gradually simplified to words that his participants were more likely to use: “What makes this particular piece of art good?” (p. 3). The study had two stages. In the first sixteen students from three schools were asked to bring two works they considered *good*, and explain their choice. Then they were shown a number of art pieces the researcher had selected and asked their opinion. In the second stage participants from one of the schools were invited to a workshop where they could work on any project they liked in a medium of their choice with the opportunity to consult with a professional artist, if they chose. His study found that, while the bases of their judgments varied, the students did actively make judgments about art works: some responded primarily to texture or color, some to implicit story, others to technique, still others to personal, family or cultural associations, and some to recognition of a famous name. The workshop component found commitment as well as variation in students’ ways of approaching art-making: some were concerned predominantly with technical process and others with imagery or narrative intention. The research report concludes with a discussion of the need for primary teachers, who tend to be generalists rather than subject specialists, to learn what students themselves think and value in order to achieve the goals of the curriculum and to develop the human right to access art that is asserted by the UNESCO *Road Map for the Arts* (UNESCO, 2006).

Using art to share findings of research

In many cases the use of art may be a final stage in the process of research: the sharing of findings. Sometimes the plan for an art based presentation is an integral part of the project. Verbatim theater (Soans, 2015; Brandt and Harcourt, 1994) and ethnodrama/ethnotheater (Saldaña, 2016; Sallis, 2003) are two performative events that are constructed out of careful research. The exact use of participants’ words in interviews is a feature of both. Verbatim theater presents itself primarily as a theatrical event and ethnodrama as research. The theater art form of both provides a platform for re-telling real people’s stories to highlight social problems and issues of social justice.

Sometimes researchers whose projects do not begin with the intention of making art might later turn to art as a means of sharing their findings with audiences outside the academy.

Hasnat (2017) studied the (dis)engagement of rural parents in Bangladesh in their children’s education. The data revealed not only a lack of engagement but also a major communicative gap between rural parents and teachers in local schools. His research project was not arts based and he submitted a formal written thesis. Later, however, he re-presented his findings as puppet theater. Two puppets were made from wooden spoons with the handle of one covered with a t-shirt and lungi and that of the other in a suit. The first represented the parents and was given dialog from verbatim data gathered from all the parents interviewed. Similarly the second, representing teachers, was given dialog from the teacher interviews. An overhead projector offered contextual images and occasional commentary. One reason for the performative presentation was to highlight the human aspects of what tends to be seen by policy makers, and some academics, as a statistical problem. An equally important motivation was to develop a means of sharing findings in a way that would be accessible to the people at the heart of the study and lead to further discussion by them. Many of the rural parents are not literate and although the teachers are literate they are not expected to read an academic report in English. The script was first published in a journal as an experimentation with art-based research (Greenwood and Hasnat, 2017) and then offered as live performance at a conference (Hasnat and Greenwood, 2018). The teachers in the conference audience actively debated the issues presented, relating them to their own, albeit different, contexts. Hasnat then planned to translate the script into Bangla on his return home and to present it not only to rural audiences, but also, if possible, to policy-makers who are unlikely to read any academic reports of research. So far Covid has interrupted this enterprise.

Tisi (2019) investigated how immigrant parents in Christchurch, New Zealand *teach* culture to their children. She considered both their strategies for maintaining the family’s original culture and the ways they positioned themselves and their children in terms of the culture they had immigrated into. Hers was also a written thesis, but she sought to bring her participants’ narratives to life by creating portraits of them and developing dramatic monologues from the interviews. After she had drafted the first monologue she trialled it in a live presentation at a conference. Teachers there suggested they would find such monologues useful for developing multicultural awareness. The feedback gave her confidence to continue with her plan. To preserve participants’ anonymity she photographed herself dressed in their style and surrounded by similar objects to those in their homes: the photographs were then turned into paintings. Each dramatic monologue used a careful selection of the participant’s verbatim words and she performed one of the monologues in her oral examination. She plans now to further develop a theatrical piece using the monologues.

These two examples highlight the role arts can play in making research findings accessible and interesting to those who are not academics but for whom the research is most relevant and potentially useful.

Using art to collect data

Arts can be useful in eliciting and collating data that may not be readily verbalized by participants. Photo voice (Wang and Burns, 1997) has become a widely used process that gives participants cameras and asks them for images that they find are meaningful in

relation to the topic being investigated. Alam (2016) asked teachers in his study to photograph what they considered effective practice and students to photograph what they valued most about their school. Both groups later talked about their images.

The taking of photographs allows a different kind of process than a simple interview: participants are given time to think about their response and they may be able to suggest something in a photograph that they cannot readily express in words. Often words are found later as participants explain and discuss their images, individually or in a group. The image continues as a presence during such discussion, inviting further speculation and perhaps new insights.

Other modes of representation might be used to elicit data, such as physical images, movement, stories, improvisations. In debriefing my students after their first school practicum I often use physical prompts. For example, I may ask them to make body sculptures of some aspect of their experience, offer interpretive readings of one another's images, and further refine their own if they want to clarify their meaning. Or I may place a chair in the center of an empty room, nominate a succession of significations of the chair (such as confidence in answering students' questions, managing unruly behavior) and ask them to place themselves at distance to the chair that would symbolize their feelings. They would then explain their positions to their nearest neighbors. I find that such activities allow participants to process their responses a little more than if they are simply questioned.

With those who cannot verbalize well, because of age, language difference, trauma or other constraints, the opportunity to offer visual or embodied information is particularly valuable, but often requires specialist expertise in interpretation.

Research may also investigate existing items of art. An early New Zealand play, *For love of Appin* (Mulgan, 1920) speaks of the split in the colonial psyche: a sense of still belonging to, but being far from, the homeland of Britain and the beginnings of realization that home could be in New Zealand. New Zealand identity is represented in the play in terms of the hard work of a farming life, the right to work one's own land, the importance of women as partners on the land, neighborly support and a sense of egalitarianism. At the same time that identity is presented as a homogenously monocultural one. There is no sign or mention of Māori or of any of the other immigrant groups that were significant at this time in the colony. So too the plays, poetry, sculptures, paintings of ancient Greece, medieval England, Franco's Spain offer researchers insights into the attitudes and perspectives of the time that are not necessarily recorded in other archives.

The current global proliferation of images of masks, including the photograph described in the introduction, offer data of how people around the world have accepted, rejected or subverted the restrictions of the Covid era.

Using art as a different way of knowing

In explaining that art opens up wider understandings of "what it means to know," Eisner (1998) crystallized and legitimized in the academic arena what artists have always intuitively appreciated. Humans are complex beings with body as well as mind: we experience sensually, viscerally, emotionally, and arguably spiritually, as well as intellectually. Making art is an embodied activity. It involves sensitivity to the multiple modalities of experience, evolving capacity to process aspects of experience through active physically engaged exploration and a drive to express discoveries sensually and sometimes kinetically as well as often posing conceptual challenges. Some researchers explicitly engage with these qualities of art in order to *know* in a different and richer way.

Exploration of visual ways of knowing is the basis of Barrett's project as described above: she sees the art class as opportunity for students to explore, stretch and sometimes transform the way they see themselves and their world, and she wants her research to *re-mark* the art classroom as a space for active inquiry. McNaughton (2019) explored the role of art gallery educators in New Zealand. In her rationale for the study she cites Arnheim (1969) who maintained that "sensory knowledge makes language possible, since our interface with reality is through our senses" (McNaughton, p. 49). Her participants' narratives highlighted the value of hands-on activities that provide multi-sensory experiences and problem-solving opportunities. McNaughton writes (p. 260): "Gallery educators were aware that various types of thinking could be woven together to develop complex understandings in art gallery learning ... Artworks were used to connect abstract ideas to concrete sensory data ... to make [students] wonder and trigger inquiry."

In my work I have used drama-based inquiry as a process that promotes discovery through both real and imagined experiences that allow participants to adopt roles that may be very different from their personal ones, to create possibilities and to navigate challenges, and to critically reflect on stages of the proceedings. I see it as a process that enables participants to try out—to embody—different perspectives and different contexts, to unlearn as well as to learn, to explore the fracture lines of meaning as well as to develop deeper, more complex understandings.

For example, as part of a scheme to train local people as teachers for a remote rural region in the north of New Zealand I was asked to teach an intensive course about the use of drama for learning (Greenwood, 1999, 2002). The course became not only an illustration of a methodology, but also a space for the participants to examine how they constructed their reality. The first sessions were used to teach a range of drama strategies. One was *Boss of My Story*. A participant shares a story that has particular personal meaning. She then chooses members of the group to take specific roles and act out her story. She has the right to stop the enactment at any stage and redirect the actors—it is her story and she is the boss. The participants were very careful with one another's stories but they were also willing to take small risks in enacting detail that might have been glossed over in the original narrative. The storytellers watched the action with emotional intensity and some did make corrections. When each storyteller debriefed after the enactment many said they were moved by the actors bringing their story to life and talked about new insights. Opportunity to look at their stories from outside as well as from inside seemed to fracture some relics of memory and allow fresh understandings. The next sessions moved to investigating local histories.

Participants selected the history of the Treaty of Waitangi as one topic. Briefly, the Treaty is the document of the agreement that in 1840 laid the foundation for colonization and that today still actively addresses, with contentions, issues of power, rights, self-determination and the two-cultural basis of New Zealand society. The Treaty is commemorated in an annual public holiday and in that year, as in many others, there were protests. As a group the participants were initially critical of the protests, but admitted they had scrappy knowledge about the events leading to the Treaty and about its subsequent history. As they researched and experimentally enacted key elements from their research individual and group understandings repeatedly shifted, splintered, and reshaped. For instance, one participant wrestled with notions of power and political activism. At one stage he questioned why the government was encouraging Treaty awareness: "Surely they realize the radicals are going to use the knowledge to bring the government down?" Later he re-conceptualized the issue: "I'm thinking where I'm wrong is that I see the government up there—that the government should be the ones making the changes—but it's the people who are making the changes." Still later he re-considered the contribution of those who protested: "It's like jumping the queue—if you wait, you stay at the back—if you do it outrageously, you'll get to the front" (2002, p. 327). In reporting the project I contended that "as the students grappled with understanding the Treaty ... and embodying their understandings in physical images they could share with each other, they were in fact writing their own inscription of New Zealand history. They were acquiring power as well as knowledge" (1999, p. 282). Looking back, I reflect how participants' images and enactments drew on the not-yet-conscious, the liminally understood and how it was only through the interaction of makers and audience that they were able to verbally explain what they had created and what it meant.

The discipline of a/r/tography (Irwin, 2004) is explicitly concerned with capturing the experience of exploring self and the world through art practice. Its orthography indicates the practitioner's fused role of artist, researcher and teacher as well as blurring distinctions between exploration through art-making and research as an academic discipline. The backslashes also highlight the notion of fracture: understandings are seen as emergent, not necessarily integrated, and resistant to tidy verbal encapsulation.

A/r/tography makes an explicit claim to be research, albeit with different ways of conceptualizing knowledge than has been generally accepted in academic contexts. It is construed as a research approach that celebrates multiple modalities of art and uses the making of art as lived inquiry, that is as a process of remaining continuously open to finding the evolving and *in-between* spaces in ideas, feelings and meanings as they emerge through the work. Accounts of a/r/tography are often couched in language that may seem esoteric to those outside the field, in part because its practitioners draw heavily on academic theorizations to situate it firmly as academic research, but also because of the difficulty in expressing concepts that are in their nature elusive and, while temporarily describable, not definable.

The intrusion of a/r/tography and other practices that use art as an investigative process further disturb already troubled boundaries of research.

The research in arts-based research

I have deliberately interchanged the words *research*, *inquiry*, *exploration* and *investigation*. All involve search and discovery, but while they have very slightly different everyday connotations they have different academic status.

The academy is already a site of contestations. In 2011 Denzin and Lincoln stated: "We are in a new age where messy, uncertain and multivocal texts, cultural criticism, and new experimental works will become more common, as will more reflexive forms of fieldwork, analysis and intertextual representation" (p. 1). They also noted that conservative and positivist political forces, with their power of funding, continue to privilege traditional forms of peer-reviewed evidence-based research. Within this contestation, some forms of art-based research are acknowledged, sometimes suspiciously, within the academy; others are not and are more likely to be classified as pedagogy.

The teacher training project I described above was part of my doctoral thesis and reports were published in academic journals. It is considered research: research about the use of drama. However the participants were also searching and discovering. They were learning about the use of drama, but they were also using the drama for other explorations and discoveries. Similarly, Barrett's doctoral work was recognized by her examiners as significant academic research. Her examiners judged that she made a new contribution to knowledge. Her student participants also found new knowledge. Their new knowledge was about personal, and sometimes group, understandings of themselves as idiosyncratic but emplaced individuals and their relationships with their significant communities. They were also discovering new knowledge about art: that it was something they could play with purposefully rather than a teacher's pre-ordained set of standards.

Distinctions between researching and learning are blurred. Action research has long challenged expectations that research would take place first and its findings would later be applied (perhaps) to professional action. Finley (2005) explores the nexus between research and learning in her work in projects that enable ordinary local communities to critically explore and resist the politically potent discourses that oppress their lives, a process she terms a people's pedagogy. "In my work," she writes, "I seek to create esthetic spaces in which to experience transformational performances at a visceral level ... In this genre of arts-based research, the researcher attempts to involve people as experts of their own lives and to create forums or outreach to venues outside the academy" (p. 444).

It is important to remember that life and its problems exist outside the academy as well as within it. Research and discovery are important to people as well as to universities. The spectrum of current arts-based approaches offer the possibility of relevance and accessibility to ordinary people as well as to scholars.

The art in arts-based research

Throughout this discussion I have talked about art as a vital creative and critical process. In daily usage, however, the word art has a very wide range of denotations. It may refer to works that are considered as high art and prized by galleries and collectors, works that indicate virtuoso technical skills, a subject that is taught in schools, street activities, reproductions, visual artifacts generally, or the wide spectrum of creative activities including performative and verbal works as well as visual ones. It may be used in phrases like *the art of parenting* or *the art of blackmail*. Academic definitions of art tend to be more restrictive. For example, my university, guided by the national Performance Based Research Fund (PBRF) that ranks and funds universities on their research outputs, frames art in terms of creative outputs that have been shared with audiences and are endorsed by peer review and citation. Interestingly the PBRF guidelines include art for advertising and business purposes, but not for learning purposes (Tertiary Education Commission, 2018). In contrast the UNESCO Road Map (2006) avoids definition of art and rather affirms that children and adults “need to progressively learn to understand, appreciate and experience artistic expressions by which fellow humans—often called artists—explore, and share insights on, various aspects of existence and coexistence” (p. 4).

Across the examples I have discussed art in the term arts-based also has a wide range of significations: the art within specific projects may align with high art, popular media, use of a particular tool that is used by art makers, and it may draw on any one of, or combination of, a range of creative visual, performative or even poetic processes. As I understand it, two qualities are needed for the art to be a vehicle for research: craft and vitality.

Craft involves both knowledge and skill. Each art process offers both opportunities and constraints. In drama, for instance, the craft of the facilitator involves balancing space for open exploration with provocations and challenges, using role to endow participants with role, creating fictitious frames that allow risk, building tension that sparks curiosity and further inquiry, juxtaposing action and critical reflection (Greenwood, 2012). It also involves incrementally developing participants’ craft so they are able to creatively use the strategies offered. In Hasnat’s puppet theater the theatrical elements are very simple; the craft is in his strategic selection and organization of the original data to create dramatic tension and yet retain the content of his findings. In a/r/tography there is craft is moderating and unifying the dialogue between the roles of artist, researcher and teacher which while interfused still speak from different perspectives.

Brook (1972) spoke of a *deadly* theater: it is theater that is perhaps technically skillful but replicative, boring and simply not alive. If art is to be a means of research it cannot be a deadly art. It has to pulse with the excitement as well as the attentiveness of inquiry. We may use procedures inherited from previous practitioners but we can use them in ways that are sensitive to the movement of the work and the interaction of the participants, just as the potter is sensitive to the clay and to the fire.

If arts-based research is to be an effective means of developing knowledge and knowing that goes beyond that produced by more traditional means, then the art within it needs to be more than a prefabricated method: it needs to be craftful and alive.

Knowledge-making through arts-based research

Alternative ways of knowing through the arts have been discussed throughout this chapter. Here I highlight five key contributions arts-based research can make to our understandings of knowledge and our repertoires of knowing.

As mentioned, discoveries through arts-based research may be emotional or visceral as well as conceptual. It has been repeatedly argued that western cultures neglect the holistic aspects of humanness by privileging the cerebral and verbal (Irwin, 2004; Leavy, 2017; Greenwood, 2016). Connecting participants with the sensation and perceptions of their bodies and inviting them to explore affect as well as ideas is one contribution.

Another is made by the way findings often exceed definition. Some projects do report clear and specific findings (and perhaps hint of other less specific possibilities). Others result in awakenings that may still be incomplete, fractured, ambiguous or latent. Specific knowledge is undoubtedly valuable. So is awareness of that which impacts on our lives but is not so readily definable. We live in a world of ecological crisis, political upheaval, brutal war and pandemic enclosure, a world where it is hard to untangle truth from misinformation. Capacity to admit and engage with the fractured and liminal helps us live with uncertainty.

Many of the discoveries through arts-based research are primarily personal, even if reports are published. They are forms of knowing that are held within the individual and by being internalized they present capacity for action. They are also subjective. Recognition and respect for the subjective, in ourselves and in others, offers resistance to hegemonic discourses.

Discoveries through arts-based approaches are often evolving, and may continue beyond the project itself. They highlight the non-static nature of knowledge and the importance of continuous learning and unlearning.

Dealing with the uncertainties of the present and the future requires development of action-orientated ways of knowing: including collaborative capacities, practical as well as theoretical criticality, and creativity in imagining and exploring alternatives. The group work and investigation strategies in arts-based projects foster growth of these capacities.

Conclusion

I began this discussion with a photograph, and I conclude with another.

Fig. 2 Exploration.

This one is from a retrospective exhibition of my husband's work. It shows a large rounded stoneware bowl with two figures who have climbed to its rim and peer inside. Their stance suggests the arduousness of the climb. They lean into the unmapped space with curiosity and uncertainty. The work is part of a sequence of Gerry's exploration of connections between people and artifacts (Greenwood, 2021/1983). It evokes a narrative, and it plays with form and space (Fig. 2).

For me, the work offers a metaphor for arts-based research. The enterprise is an embodied one. Processes of inquiry are supported by the strong structures of art traditions and contemporary art practices. Researchers stand on the rim of what is already known and what is yet to be explored. Light and shadow play over the space for exploration. There are latent possibilities created by the selected art strategies but the space is open. The results are not predicted. The quest is an adventure.

The umbrella of arts-based research covers an eclectic and protean range of approaches to research that make it difficult to circumscribe as a methodology. Each art and each application of an art opens up different opportunities for exploration and offers different constraints to guide the work. Nevertheless there are some common features in the diverse array. They offer a multi-faceted approach to investigation, invoking a mix of physical, emotional, spiritual and intellectual responses to experiences, and so offer alternative and additional kinds of knowing from those generated by more traditional qualitative and quantitative approaches. They may generate ideas and specific new understandings but they are also open to intuitions, complexities and liminalities. They have the potential to facilitate inquiry at the level and in the manner that are accessible and meaningful to their participants and share results of inquiry with audiences in ways that are accessible and meaningful to them. Importantly, they are grounded in art practices that have long histories of exacting attention to material, form, process and evolving meaning.

Introduction

In the current context schools, colleges and universities provide a meaningful and useful preparation for life in our complex modern societies, despite consistent decreases in funding and a narrowing focus of education. The lack of success in providing an adequate education for children from lower income and culturally different backgrounds continues as a central concern in most nations. Internationally, there is continuing and strong evidence of the failure of school systems to provide an adequate education for the children of poorer and culturally diverse families. An extended analysis by [Sarason \(1990\)](#) with the telling title, “The Predictable Failure of Educational Reform,” indicated that over a twenty year period there had been no progress in a key aspect of the US national reform agenda – closing the achievement gap of students of different social classes and ethnicities. [Cole’s \(2011\)](#) more recent study covering the following twenty years found fundamentally the same ineffective results. His analysis, “What’s Culture Got to Do With It?,” indicated that reform efforts were largely ineffective and restricted to improvements in ways of organizing schools, classrooms and teaching/learning practices that had emerged in the past. He advocated changes to the culture of the classroom on general pedagogical principles and the need for organizational reforms that would support those changes.

Within Australia, continuing reports of the Council of Australian Governments (COAG) over a fifteen years period reveal a failure to make any inroads on the scandalous difference between educational outcomes for Aboriginal children, as compared with non-Aboriginal children ([Close the Gap Campaign Steering Committee, 2016](#)). Despite significant investment in special programs and services, national tests indicate that Aboriginal children still perform at the very lowest levels of tests of academic achievement, despite occasional successes in a small number of locations. The continuing application of standard approaches to schooling for students whose culture and life-histories differ significantly from those of mainstream Australian students has failed to accomplish the desired ends of “special” programs.

This chapter presents processes of participatory, community-based action research as an important means to enable educators and educational institutions – schools, colleges, universities and so on – to modify and adapt their standard educational procedures to accommodate the realities of the diverse cultures that comprise the reality of modern societies. Following sections present the rationale for engaging in community-based approaches to teaching and learning, the value of building community capacity to enrich classroom learning activities and how current resources in information technology and social media can facilitate these developments. The chapter also suggests that changes involved in school procedures are likely to have an impact beyond classrooms, requiring concurrent negotiations with school authorities.

Final sections of the chapter describe how recent developments in research theory provide strong support for engaging participatory, community-based approaches to research in order to produce curriculum content and learning activities meaningful and purposeful for the educational and social needs of students in their particular locations. By extension, we also suggest that the processes of localized research and development are particularly relevant to contexts where cultural diversity requires modifications to standardized approaches to teaching and learning to accommodate the realities of the context.

Situating community-based, participatory action research

Community-based, participatory approaches to research derive from developments in qualitative inquiry that emerged relatively recently as a legitimate and powerful set of research methodologies. These types of investigation are articulated in a wide range

of literature, including textbooks, handbooks and encyclopedias describing the general theory and practice associated with qualitative and mixed methods research. A small sample includes Denzin and Lincoln (2019), Greenwood et al. (1993), Abma et al. (2018), Charmaz et al. (2019), Chevalier and Buckles (2019), Coghlan and Brydon-Miller (2014), Denzin and Giardina (2018), Heron (1996), Kemmis et al. (2014), Schubotz (2019) and Boden et al. (2015). General texts on research in education likewise include sections of action research, recent literature including those by Sutter (2011), Cresswell and Poth (2017), Johnson and Christensen (2019), Mills and Gay (2018), Boudah (2019) and Biesta (2020).

These and others provide a rich body of theory that embodies the philosophic and paradigmatic orientations associated with the diverse approaches to research now encompassed by qualitative research. In essence they challenge some of the assumptions embedded in earlier approaches to research, describing the fundamental differences required to establish the authority of a scientific approach to research. In doing so they reveal the substantial differences between the orientations of research in the human sciences and those of the physical sciences. The demarcation between them is not fixed, however, since positivistic approaches to research often provide information usefully applied to issues in the conduct of human affairs, while issues associated with research in the physical sciences are influenced by the social contexts in which research activities are engaged.

While the above citations relate to the general theory and practice of qualitative research, a significant corpus of literature related to action research in education continues to emerge. Though each takes a somewhat different approach, and some focus on first person action research which is essentially non-participative, a current sample of recent literature includes.

Stringer and Ortiz Aragón (2021), Mills (2017), Bradbury (2015), McNiff (2017), Mertler (2019a,b), Putman and Rock (2017), Hendricks (2016), Efron and Ravid (2019) and Sagor and Williams (2016).

Localized educational practices

As Cole (2011) and Sarason (1990) have indicated, effective change in educational outcomes are unlikely to be accomplished merely by focusing on classroom practices. These have a proven record of failure, pointing to the need not only in changes to standard procedures in teaching and learning, but also changes in the associated organizational arrangements. Although carefully articulated system-wide change processes provide the best context for engaging in truly effective educational practices, in many locations teachers and administrators have the capacity to instigate developmental teaching and learning processes that engage student energy and interest and provide the basis for highly educational learning experiences. Despite continuing pressures to centralize and control all aspects of schooling, participatory and community-based approaches to research have the potential to initiate more locally relevant educational programs and practices. For example, Barrett (2007) describes ways of conducting qualitative research in music education. Nah and Lee (2016) describe how action research was used to actualize children's participation in the development of outdoor play areas in an early childhood institution. Calhoun (1993) describes how action research can enhance the processes of educational leadership, while Hendricks (2016) describes the use of action research as reflective practice for school improvement. In similar vein Wells (1994) suggests the need to create communities of inquiry to change schools from within.

In our own spheres of work we have learned, with and from local people, how to modify and adapt learning processes to tie them more clearly to the contexts in which they are played out. Early in his teaching career, Ernie discovered that the Aboriginal students in his classroom, so silent and unresponsive in the classroom, came to life when he walked with them through the surrounding bush-land and learned from them all the wonders of the flora and fauna with which they were intimately connected. Using these as the basis for lessons in the classroom, his students became his teachers as they expounded on the knowledge with which they were so familiar (Stringer and Ortiz Aragón, 2021).

In a similar context (Stringer, 2015) observed a high school teacher, saddened by her unresponsive students, engaged them in a range of activities drawn from the local community. As part of her class program she made representations to the local police sergeant who sent officers to the school to speak to her class about their work. Students also visited the police station where they learned many features of police work, including processes for dealing with miscreants and the duty of care they had when an arrest was made. In the process students developed relationships with the police officers and came to better understand the nature of police work, including how it derived from legislated laws rather than the decisions of individual officers. The outcomes of this process were a better understanding of the operation of the law and a better relationship between police and youth in this small community. All these were encompassed within a carefully articulated program drawn from the state curriculum: (Fig. 1)

Wood and Govender (2013) report on the way a group of South African school leaders were able to promote sustainable development and improvement within the challenging contexts of their under-resourced school communities. Stringer (2008b, 2015) reports on a highly successful action research project in East Timor, where school authorities used participatory action research processes to engage local communities in the redevelopment of their school system when that small nation received independence after a long struggle with colonization.

The essential dimension of community-based participatory research is that it is not done *on* people, but *by* and *with* people who have previously been designated as *subjects*. In one highly successful research project Ernie assisted a neighborhood group in their local elementary school in a largely Hispanic suburb of Albuquerque in the US to engage in an action research project. Concerned about the quality of education provided for their children members of the neighborhood group sought to discover ways in which parents and teachers could improve the school experiences of their children. The neighborhood group recruited other parents and practiced interview techniques under direction of a university professor, then interview parents who came to school

for parent-teacher day. The results emerging from the participatory processes of analysis that followed provided a list of practical actions that teachers and parents could take to improve the children’s schooling (Stringer, 2008a).

Building community capacity

Much educational research continues to focus on classroom practices on the assumption that identifying “best practices” will provide the answer to enduring problems in education. Despite a continuing focus on the individual attributes of students, large scale studies dating back many decades indicate that despite the importance of classroom and school variables, the major part of variance in educational outcomes relates to family and community factors (Coleman, 1966, Alexander and Morgan, 2016). As this chapter previously has indicated, changes in educational or academic performance might best emerge from a closer alignment between the school, student families and the local community. Occasional events that invite families and community into the school are insufficient to accomplish the strategic activities required, however, and the following narrative describes the potential for developing intentional and long-term relationships with parents and community members. Not only do parents become increasingly aware of the nature of school life, but school staff build a better understanding of the life-worlds from which their students emerge.

These issues became evident to Beadle (2018) who discovered that a school breakfast program operated by a group of women in a remote Aboriginal community had multiple benefits within the classroom, the school and the community. In a context where test results of student academic performance in the local community were among the lowest in the nation, a group of local Aboriginal grandmothers, aunts and mothers initiated a solution for enhancing attendance and engagement in the school. They recognized that the school was not effectively addressing the needs of their children and their regular absences were a cause of concern,

We were worrying for them tjitji (kids). We wanted them to go to school and stay in class, not be running away all the time. It’s important for those kids to get learned, you know, grow up and get a job proper way, like the Breakfast Minyma

Breakfast Minyma (2012), pers. comm., cited in Beadle (2018:60).

Assisted by a developmental support worker a series of meetings were held between the women, local Council members and the school principal at which the idea of providing breakfast at the school took shape. Within a few weeks the project was launched, an efficiency that contrasts markedly with projects externally initiated and managed by non-Aboriginal “outsiders”. As well as having a positive impact on children’s attendance, by coming to the school each day to deliver breakfast the women became a strong presence at the school where almost all school staff were non-Indigenous “outsiders”.

The women’s daily presence meant that relationships could develop with school staff who previously had experienced very little interaction with their pupil’s family members. Most of the teachers had lived in cities, so the context in which they now worked and lived was alienating and unfamiliar, something that prevented relevant and effective teaching. The presence of the women acted as a “gateway” to the local community, enhancing the teachers’ understanding of community life and providing access to information that could assist their teaching and relationships with students (Beadle, 2018). This enabled them to reconfigure their programs in a way better suited to the needs of the children and gain a better grasp of the causes of the many challenges they faced in the classroom.

Fig. 2 A page from "mirlirtjarra Kuurl Mirrka Palyalpayi (Making Good Food at Warburton School)" by Olive Lawson.

The women became known as "The Breakfast Minyma" and acted as an informal Aboriginal reference group for the school principals. They were consulted about issues such as appropriate disciplinary measures, how to attract community members to school events, and determine solutions to matters such as school uniforms and school security. After the school breakfast had finished the women would sometimes accompany the children into their classrooms, an activity that had previously been well outside their comfort zone. As a result of these experiences some of the women were then invited to work as Aboriginal Education Officers (AEOs),¹ further enhancing the presence of local people in the school. The Minyma reflected positively on the impact of their presence in the classroom, and the way they had a natural authority over the kids, something the non-Aboriginal teachers sometimes struggled with.

When I am in the classroom [as an AEO (Aboriginal Education Officer)] I feel good, happy with the kids. It's important there is an AEO in the classroom. So you know, when the teacher can't tell the kids to sit down when they run around and make the teacher talk [get frustrated]. [But] the kids, they always listen to me, I tell them in language and they listen.

Breakfast Minyma (2012).

As the women established themselves as valued and productive workers and broadened their knowledge of day-to-day life at the school, their increasing confidence led them to explore additional ways of enhancing their children's educational experience. They engaged in collaborative planning with the teachers and ran a series of "lessons" framed around their own experiences as workers. These were delivered in the local language using techniques that were so successful that one teacher commented "I've never seen the class so attentive!" (Teacher 2011, pers. comm. cited in Beadle, 2018:170).

Because so few of the textbooks employed by the teachers included or acknowledged local events or cultural experiences, the women responded by developing a set of nearly thirty bilingual "story" booklets, using content derived from their experience as workers. In addition to making books about their work, they assisted other groups in the community to produce books that covered a variety of topics about community life. Feedback from teachers and the principal indicated that these were popular reading materials among the children. While the English text in the booklets reflected the literacy requirements determined by the school curriculum, the content and translations into the local language gave value to the children's remote desert lives and resonated with their cultural experiences. This contrasted with the externally produced "age-appropriate" readers with unfamiliar topics such as "Katie and her grandmother take the train to the beach" provided by the school. The importance of these books was demonstrated when the state Minister for Education launched their first book in Perth, her department offering financial support for the women to travel to the event (Fig. 2).

In addition to books, the Breakfast Minyma developed PowerPoints and short documentary films which they used during their lessons. They recognized the relevance of these learning materials for their children, one commenting that:

¹AEO's were equivalent to Teaching Assistants.

When we are showing them the photos and the movie the kids say: “Oh, that’s my karparli!” “Oh, that’s [child’s] Mummy!” It makes them feel proud looking at the pictures of what their families are doing. It’s good for the kids, to see the photos, watch the ladies. Like they want to learn, when they grow older, they see the photos, they see the family working there, they get happy the kids, *yuuu* (yes), and when they must finish school, [they will] get a job you know, like the ladies too

Breakfast Minyma (2012), pers. comm., cited in [Beadle \(2018:169\)](#).

In these and other ways the mothers and grandmothers began to understand more clearly how their children were expected to participate in a classroom shaped by a curriculum and social context controlled by the norms of the dominant culture. Observation of and feedback from their children, as well as their own student experiences in school had provided the women with a deep understanding of their children’s struggle to understand the rules, codes and social norms expected of them by their teachers ([Minutjukur and Osborne, 2014](#); [Tjitayi and Osborne, 2014](#); [Beadle, 2018](#)). As opportunities allowed, the women therefore oriented their school activities in a way that acknowledged the “deeply embedded axioms, epistemologies, ontologies and cosmologies” of their life-world ([Tjitayi and Osborne, 2014](#)). In the ways articulated above, they were able to make a positive contribution to their children’s schooling by delivering their programs in a way that observed the deeply engrained relational component of community life, conversing in their own language, and addressing behavioral issues -such as teasing - in a culturally appropriate way.

In these ways the women improved the children’s learning experiences by modeling their own ways of teaching in their family environments. In doing so the women provided what [Tjitayi and Osborne \(2014\)](#) refer to as “close family voices” that enabled the children to participate more confidently in classroom and school activities. Recognizing the familiarity and comfort their presence offered the children at the school, the women described their school-based workplace (The Family Place) as a “magnet”:

The Family Place is like a magnet pulling them kids. It’s really good that those kids hang around. At recess and lunch time the kids run to the Family Place to be with their families. That’s making them hang about at school instead of going home

Breakfast Minyma (2012), pers. comm. in [Beadle \(2018:90\)](#).

The status, pride and self-esteem the Minyma gained from their work led them to initiate solutions to address other concerns regarding the wellbeing of their families and community. Other projects and services to emerge included the provision of meals for elderly people in the community, an evening support program for teenage girls, and catering services for community and school events. In broadening their repertoire of activities, and thus the scope of their work in the community, the Minyma further consolidated their role as “workers”. In a context where Aboriginal voices are typically marginalized, the respect and authority they experienced as workers gave them the confidence to share their stories with a range of audiences at conferences and other events in the city. These stories helped dispel prominent “mainstream” narratives which rarely represent remote Aboriginal people as valued and productive workers.

The Minyma’s self-initiated activities within the school demonstrates the importance they attributed to the educational wellbeing of their children and their desire to incorporate local language and culture into their children’s learning. As is common in many other contexts where there is disparity between the cultures of the teachers and students, the prevalence of local people in this remote Aboriginal school helped dissipate what [Delpit \(1993\)](#) describes as a “culture of power” ([Tjitayi and Osborne, 2014](#), p. 29). In many ways this had a significant impact on the relationship between the school and the community, creating the context for greater interaction between the staff and family members who, over time, built the capacity of people in the community to enhance the education of their children.

Using information technology and social media for community based action research

The above narrative, in which a group of local Aboriginal women were able to communicate stories and presentations about their activities provides an example of the striking developments in information technology and social media that have emerged in recent years. [Kent et al. \(2021\)](#) review the extensive possibilities whereby social media applications can be used by educational practitioners to engage students, parents, community leaders and local people in their projects. A small sample of these uses of technology includes the following:

- [Annamalai \(2018\)](#) reports on the use of WhatsApp to investigate pre-service teachers’ online activity.
- [Arihastha and Basthomit \(2019\)](#) describe how project -based learning, process writing and Instagram were used to enhance student writing skills.
- [de Jager et al. \(2017\)](#) review the different ways of digital storytelling was used to enrich their research.
- [Latz \(2017\)](#) provides a practical guide to the use of Photovoice in education, while [Ha and Whittaker \(2016\)](#) provide a case study describing how this application was used to enable children with autism spectrum disorder to tell their stories.
- [Sirin et al. \(2018\)](#) describe digital game-based approaches to education for vulnerable Syrian refugee children.
- [Pereira et al. \(2019\)](#) describe the use of Second Life to develop clinical reasoning skills.
- [Saeed and Yang \(2008\)](#) describe how blogs, social bookmarks, and podcasts can be incorporated into unit teaching.

- Raj et al. (2019) suggest processes for using YouTube as a platform to learn social expression.

A strand of projects involving social media demonstrate how research can be used for purposes of social activism:

- Kunnath and Jackson (2019) describe the development of student critical consciousness, using Twitter as a tool to apply critical literacy in the English classroom.
- Mayorga (2014) describes movement toward digital, critical, participatory action research.
- Bogle (2019) describes how kids are using TikTok to politically organize, a high-profile example of this emerging during the run-up to the 2020 presidential elections in the US.
- Mitchell et al. (2017) also describe how participatory visual methodologies facilitate social change through community and policy dialogue.
- Trott (2019) describes the processes of collaborating with children for community-based climate change action.
- These activist-oriented approaches to educational development have associated theoretical framings, such as those presented by Orłowski (2019) who describes how Freirean conceptions of participatory inquiry may be used for teaching about social justice.

More broadly, Stringer (2015) and Stringer and Ortiz (2021) provide examples of highly successful community-based action research projects that used multi-media and performative presentations to achieve strong outcomes for Indigenous populations in Australia, Hispanic groups in the US and school development in East Timor. In these and many other contexts social media and information technology provide the means to strengthen links to local communities and to include stakeholding audiences – students, colleagues, administrators and community members – in rich and effective educational projects.

Culture, curriculum and pedagogy

The development of culturally appropriate education practices requires a deeper understanding of the nature of culture that would enable local schools to modify and adapt centrally devised curricula to the realities of everyday life of local families and communities. There is a sound theoretical basis for accepting the logic of this dynamic, since child development has long been recognized as being intimately associated with culture, the way children think and learn – their cognitive development – being primarily linked to the context of their cultural environment.

Piaget described how children build cognitive structures – mental maps, schema, or networked concepts – by responding to experiences within their environment: people, objects, language and culture (Piaget and Inhelder, 1969; Wadsworth, 2019). From Bruner's perspective, culture shapes the mind and provides the toolkit from which children construct their worlds and a conception of themselves (Bruner, 1974, 1997; Illeris, 2018). Perhaps more specifically, Vygotsky saw culture as the prime determinant of a child's cognitive development, and language and social interaction as key processes associated with learning (Vygotsky et al., 1978; Vygotsky and Kozulin, 2012; Moll, 2013). The culture that children learn provides the particular schema through which they are able to understand the world in which they live by engaging the enduring patterns of thinking, behaving, believing and valuing that are largely established in the first years of their lives.

Culture, for each individual in a social group, includes an embodied understanding of what *is* – concepts that define reality, what *can be* – systems of belief, what *should be* – systems of value, what *to do* – acceptable behaviors and actions, and *how to do it* – acknowledged methods or recipes for accomplishing a set of designated outcomes. Culture, however, not only provides the context by which people act out their day to day lives, but it is also a deeply embodied set of precepts through which people define who they are – their identity. This, in turn, provides them with the basis for defining their inner life—their concepts of self and identity—issues that cannot be taught as “lessons” but that are implicit in the ongoing interactions and activities embedded in their social lives.

At all levels of education, current procedures for establishing both curriculum content and teaching/learning processes tend to ignore these fundamental features of the students life-world. Curriculum development is treated as highly centralized activity by state, regional or national education authorities, with panels of experts and community leaders establishing content areas with an increasing emphasis on specifically designated pedagogical processes – direct instruction, testing regimes and so on. School systems establish parameters for the implementation of a state/regional curriculum and administrators and teachers at the local level work within the guidelines thus established (See Fig. 3). The result is an educational experience established according to the expertise and cultural life-world of a largely professional elite that often has very little understanding of the cultures that daily walk into the schools and classrooms in the form of the children, the living manifestation of the diverse cultures that comprise modern social contexts. In such circumstances the “cultural fit” of curriculum and pedagogy will be determined by the extent to which a student's cultural world is consonant with the cultural world of those responsible for developing the curriculum and the teachers and school administrators responsible for its implementation.

Further, however, those responsible for implementing these educational arrangements are subject to continuing pressures to comply with directives to organize teaching and learning according to issues dictated more by the financial and organizational needs of the institutions than the realities of student educational, social and cultural needs. Despite these restrictions, however, participatory and community-based action research processes have the potential to enable teachers and administrators to implement educational processes that are relevant, engaging and educationally productive. They hold promise of providing educational programs not only meaningful in terms of employment, but in service of the more human features of social life that value the identities of the children and provide the creative and artistic energy so essential to people's well-being (See Fig. 4).

Fig. 3 Curriculum planning.

Fig. 4 Community-based curriculum planning.

As previous sections of this chapter suggest, participatory and community-based approaches to inquiry have the potential to inform administrators and curriculum leaders of the social and cultural make-up of the community, an essential aspect of a rich and comprehensive curriculum. This information is unlikely to be found in libraries or any other collection of texts, since the narratives associated with reports and descriptive materials are essentially limited, providing little of the empathetic understanding of the diverse life-worlds of the community that could provide the basis for a truly human and democratic curriculum.

Organizational and systems change: implementing holistic developmental processes

The issues raised in the opening section of this chapter have been amplified in recent decades by the gradual integration of a powerful ideology into the governance and operation of social systems across the world. A range of intellectual commentaries describe how neoliberal ideologies promote visions of social life determined by economic imperatives driven by market-based social

processes in which: “the techniques and values of accountancy have become a central organizational principle in the government and management of human conduct – and the new kinds of relationships, habits and practices this is creating.” (Denzin and Giar-dina, 2017). The language and processes of accountancy thus provide the basis for an audit culture in which the logics of the market structure life in the new neoliberal education system (Smart, 2010).

School systems likewise have been impacted by the application of neo-liberal ideologies. Within education, performance metrics on nationally standardized tests are used to calculate status in local and national rankings, providing the means to evaluate the well-being and worth of each school and each group of students. In some contexts, these metrics also provide the basis for determining not only the rank of the school, but also at the level of the individual, rewards in the form of promotion and/or salary. In some instances, failure to accomplish expected outcomes in school settings, may result in reduced funding for the school or reduced prospects/salary for individual teachers and administrators.

These processes, now well established in many parts of the world, have made little difference to the inequitable outcomes of existing education systems, despite sometimes massive efforts in the form of special programs and services. Ultimately the systems look for change in the pedagogical or organizational arrangements within schools, or place blame on teachers, entire schools, students or their families. What we suggest, however, is the need for rearrangements that more clearly fit the systems to the educational, social and cultural realities that make up the life-worlds of the students, rather than the reverse. This means, in essence, that those responsible for the operation of school systems invest some of their time and energy in understanding the social and cultural realities of people at all levels and groups within their locality in order to incorporate the strengths of their communities into the curriculum and the operation of the system.

Change, however, is something that cannot be achieved by focusing on classroom pedagogical practices, but needs to reach into all levels of a system (Harrison et al., 2019) rather than interpreted as something that can be added to existing arrangements, sometimes referred to as “spray-on” or “silver bullet” solutions.

Kelly and Westoby (2018) provide a powerful framework that describes the processes required to integrate changes through all levels of any social system:

- *Implicate level*, in which individuals reflect on changes that are needed in their own approaches to professional practice
- *Micro-level* which entails building purposeful relationships that enable people to interact productively with the diverse people they engage in their work and community contexts
- *Mezza-level* refers to effective ways of engaging participative processes with small groups
- *Macro-level* focuses on ways of forming and operating strong organizations that enable people to accomplish large-scale projects
- *Meta-level* development entails the integration of personal, group and organisational processes to accomplish large-scale movements at national and international scales, often accompanied by philosophical and ideological developments.

Though there is a tendency for people to state that “we’re already doing that”, developmental processes actually require carefully articulated human technologies, enabling practitioners and administrators to modify and adapt the centralized, hierarchical approaches to organization and development currently dominating many areas of social life. There is a general literature that supports these approaches to social, organizations and systems change. Checkland and Holwell (1997) describe the use of information systems to make sense of the field; Checkland (2000) reviews the use of soft systems methodologies over a thirty year period; Checkland and Poulter (2006) show how systems methodology might be used by professional practitioners, teachers and students; and Flood (2010) and Ison (2008) illuminate the relationship between action research and systems thinking. All point to the need for systematic professional and organizational development across all levels of a system.

Ethics in participatory and action research

Ethical issues have been particularly problematic in community-based, participatory and action research, since these approaches to research seem to contravene a number of issues previously thought to be basic to the uninvolved stance required of rigorous experimental and quasi-experimental research. A key challenge in participatory research related to the need for the development of appropriate protocols and practices for ethics, the need to balance participatory processes with the need for individual safety, security and confidentiality require carefully articulated ethical procedures. Furthermore, issues related to duty-of-care for research participants and the need for confidentiality are both seemingly problematic in action research, where sharing information and systematic interaction between participants often is essential. More recently academic researchers have presented ways in which academic ethical requirements can be accomplished systematically within an action research process. Banks and Brydon-Miller (2018) present a detailed analysis of issues related to ethics in participatory approaches to research, while Brydon-Miller et al. (2015) demonstrate how structured ethical reflection can widen the circle of participants and increase the power of an action research process.

Conclusion

Continuing movements in education to centralize decision-making and standardize curriculum and pedagogical arrangements have failed to produce improvements in educational outcomes for students from marginalized and culturally diverse social groups. Market-based educational arrangements continue to undermine the possibilities for more humanly productive education systems

that improve the social and cultural well-being of the diverse cultures they serve. Despite these restrictions we contend that the techniques and technologies of the current era provide many possibilities for local-level, participatory approaches to research that builds on the strengths of local communities and provides a more relevant, engaging and productive experience for all concerned – students, teachers, administrators, families and community members. These interactive approaches to education not only strengthen the educational intents of schooling, but also provide the means to develop the capacities of individuals, families and the broader community to deal with the complex web of issues that characterize the reality of today's social worlds. More particularly, they also provide the means to explore the possibilities of opening the rigidities and power-driven processes of many education systems to the creative and life-enhancing qualities inherent in the human spirit. Our experience suggests that even small projects have the potential to extend their power and reach to eventually be the seed from which significant changes emerge. In the words of an Australian songwriter, "From little things, big things grow."

Introduction

Oral traditions, including storytelling through folktales, legends, jokes, songs and chants, proverbs or wise sayings, and mythologies, have existed for millennia as vehicles for intergenerational transmission of culture and knowledge. Indigenous and local oral traditions are considered to be less prescriptive in their approach, embody a more relational epistemology, and balance the power dynamics between the researcher and those who share their knowledge. The researcher becomes a knowledge sharer as well as a knowledge gatherer and is likely to be grounded in the culture in which these traditions take place (Nakhid, 2021; Fernández, 2020). In recent years, oral traditions have been used to inform education research, providing an inclusive approach to engaging with academic communities where orality is a salient way of constructing and sharing knowledge. The use of oral traditions in research enables agency for those involved in this process (Nakhid, 2021). As such, oral traditions embed an Affirming Methodologies approach to research by affirming practices that are grounded in peoples' lived realities and worldviews.

An Affirming Methodologies framework centers local and indigenous practices of knowledge construction on the premise that they are likely to result in greater authenticity and accuracy. Nakhid (2021) and Nakhid-Chatoor et al. (2018) argue that local and indigenous research methodologies should present from within their own living experiences and realities—even as they hold an awareness of the impact of western and colonial research practices.

The first part of this paper defines the concept of Affirming Methodologies. Selected oral traditions are then conceptualized as affirming methodologies that ground research in the culture, lived experience and worldviews of those involved. Ole Talk, a Caribbean oral tradition that has been recently explored and utilized as a research method, is described to illustrate its potential for enabling culturally affirming knowledge construction and sharing.

Defining Affirming Methodologies

Affirming Methodologies is a theoretical, epistemological, and methodological concept which frames indigenous and local practices of knowledge construction as valuable in and of themselves. An affirming research methodology is centered on the strength and uniqueness of local and indigenous knowledges and emphasizes the value of culturally relevant and local ways of knowing (Nakhid and Farrugia, 2021). When conducting research with Indigenous, Black and People of Color, Affirming Methodologies enables

awareness and acknowledgment of how their histories, traditions, and local evolution have shaped their knowledges. The research approaches are grounded in practices that are culturally relevant and suited to their own cultures and the cultures of those with whom they work (Te Awakotuku, 1991; Castellano, 2014). Oral traditions and methods are seen as affirming methodologies when they elicit authentic knowledge that resonates with communities and are of value and relevance for the community in which the research takes place.

Indigenous communities have a right to select their preferred method of data collection (Drawson et al., 2017). Some existing research practices have been modified to meet the needs of communities incorporating “indigenous values, beliefs, and ways of knowing, facilitating research that is respectful, collaborative, and relational” (Wilson, 2001). Methodologies that are affirming utilize the specific modes of being and knowing of the communities where research operates, and their methods, techniques and tools respond to the continually evolving realities, practices, experiences, and aspirations of those communities.

Affirming Methodologies acknowledges and celebrates intersections and solidarities with other communities (Fernández Santana et al., 2019). With an affirming methodological approach to research, culturally relevant ways of knowing are presented as valuable within themselves and not in comparison to dominant Eurocentric approaches to research. Affirming Methodologies centers local voices previously excluded from mainstream research and allows for the building and developing of relationships among knowledge sharers (Nakhid, 2021).

The significance of oral traditions, and as affirming research methodologies in education

Oral traditions are classified by UNESCO as part of a country’s intangible cultural heritage, along with diverse practices that range from traditional dances to weaving and fishing (UNESCO, n.d.). The word *oral* gives the emphasis to oral tradition and oral narratives and, although it sometimes refers to speech and words, it needs to be applied cautiously so as not to exclude sign language and body language (Finnegan, 2003). Oral traditions are the memory of a people encompassing those aspects of life regarded as important within their culture. Tradition is a term frequently used by anthropologists, folklorists, and oral historians to refer to culture or an established way of doing things; the process of handing down practices, ideas or values; or to mark out a group’s identity. Oral traditions can be described as cultural heritage and practices that are shared and passed down intergenerationally through non-written communication (e.g. storytelling, conversation, sayings, songs, etc.). Oral practices are valued and important components of a culture and can be defined as traditions when they present a long-standing legitimacy in that community and are shared widely among its members (Finnegan, 2003).

Oral methodologies and methods are frequently preferred in research with indigenous and non-western communities, or those who have had their cultures and lives misrepresented by western mainstream research practices. Oral methodologies contribute to ensuring that a research practice is inclusive, respectful, and affirming of local and indigenous beliefs and communities’ ways of living and knowing. This has the potential to generate more authentic and locally grounded research results that can be accessed and used by the community where the knowledge was generated, thereby preserving ownership and agency. Mahuika (2012) argues that we need to navigate and analyze our world from our own knowledges and understandings if we are to have a true assessment of our realities.

The use of oral traditions as culturally affirming approaches to knowledge construction constitutes a shift away from mainstream research as follows: First, oral traditions are firmly grounded in the realities and communities from which they emerge. Consequently, when oral traditions are used in research, participants are likely to be familiar and comfortable with the modes of engagement. This creates an environment where subjects can draw on their cultural competencies and strengths to engage in knowledge construction as active agents.

Second, although they are dynamic and constantly evolving, oral traditions typically encompass practices and worldviews shared by their community. Thus, when oral traditions are used as a foundation to design and conduct research processes, the researcher is de-centered and is no longer the sole custodian of the “rules” of knowledge construction, but a subject building knowledge alongside other subjects.

Third, oral traditions are authentically interwoven in a culture or community. When research is designed around a community’s oral traditions, the phases of research flow organically. This avoids the need to “bridge” foreign engagement practices with local ways, a difficult and ethically questionable task for researchers, especially for those working in their own community employing culturally unrelated western mainstream research methodologies.

Oral traditions in education research

For Indigenous, Black and students of color, self-determination and identity affirmation are inherent in oral research methodologies and enable these students to politically express and assert themselves in what might be a hostile classroom environment (Mahuika, 2012). Oral research methods allow school communities to see the different ways that students perceive the world in which they live (Mahuika, 2012). They have the potential to be transformative for those students and staff typically marginalized by the school curricula, administrative systems, and regulations by opening the way for those in dominant positions to conscientize themselves and challenge the policies and processes in place that have constrained the opportunities of certain groups (Navabi, 2006).

Oral research methods give students the opportunity to use poems, legends, songs, and myths to share their experiences in a manner that more acutely expresses their academic life (Kargbo, 2008). Oral research methods allow for information to be validated by other students in a non-confrontational setting and give rich data that may not be possible to obtain through quantitative research methods (McAdoo, 1980). Oral research methods can also study interactions among students, and between students and teachers in group settings such as liming whereby ole talk can be used to address conflict and negotiate expectations (Nakhid, 2022).

For many of those failed by an oppressive education system, oral traditions have been their ways of passing on knowledge through the generations. The recognition for these students that comes from knowing that oral traditions illustrate a formidable and enduring mental capacity and fortitude, and that they are invaluable and sacred approaches to holding and sharing trusted and sustainable knowledge, is critical to how they value and advocate for their voices in the academy (Struthers and Peden-McAlpine, 2005). More so, oral traditions used in education research studies connect and strengthen solidarity among different marginalized groups. Critical race methodology sees oral research methods as a way that students of color can reveal and document their education journeys to benefit not only themselves but those students that come after, so that they are aware and knowledgeable of those and their systems that have attempted to marginalize and silence them (Solórzano and Yosso, 2002).

Storytelling: embodying the oral traditions

The use of oral traditions as research methodologies in education and other disciplines is underpinned by the notion that storytelling and conversation are powerful means of constructing, sharing, and preserving knowledge. Storytelling is seen as one of the more common research methods associated with oral traditions and has become increasingly valued and employed in contexts where Eurocentric ways of knowing are seen as culturally irrelevant or inappropriate. Storytelling is invaluable to how knowledge is sustained and protected within Indigenous communities. A story tells who we are and are “stories of origin and of ancestors, world view, values and knowledge for everyday survival” (Koukkanen, 2000, p. 421). Traditional storytelling is a “way of expressing Indigenous knowledge, culture, and oral traditions that privileges holistic interconnectedness, collaboration, reciprocity, spirituality, and humility” (Datta, 2018, p. 36). In Indigenous culture, stories are a common repository of knowledge and facilitate the process of knowing (Ware et al., 2018).

In recent years, Indigenous scholars in education have taken an interest in storytelling (Archibald, 2008; Kovach, 2009) and many indigenous research methods and methodologies involving storytelling have been documented and disseminated (Kovach, 2010). In research using storytelling, the relationship and what is created between the researcher and participant are important considerations (Dyll-Myklebust, 2014). Storytelling and conversations are seen as culturally affirming research methods in the way that they center local knowledge and ways of knowing.

Rodriguez (2010) has observed that storytelling can assist researchers build more meaningful relationships with students of color. These relationships can enable researchers to disrupt any racist messages that students of color might receive in white school settings and to share their own experiences of racism without minimizing but rather validating the students’ experiences. Counterstories, as Solórzano and Yosso (2002) suggest, can be used in education research with students of color to challenge racism, sexism, and classism and any tales of deficit that disadvantage the students.

Storytelling informs many of the oral research methods and methodologies currently used by local and indigenous communities, some of which are described below. Although this list is not exhaustive, the selection of these methodologies and methods is based on those characteristics similar in the practices across communities: authenticity, inclusiveness, shared connection, relationship, reciprocity, ownership, and equity.

Ubuntu storytelling

“Ubuntu storytelling is about engaging our relational selves” (Mucina, 2011, p. 1). Ubuntu, says Mucina, is a research method where we relate to each other through storytelling. The Ubuntu (people) use the art of oral storytelling because a “story can allow a culture to regenerate itself” (p. 1). Hall (1997) notes that the continual process of knowledge making is essential to living as a human being. Mucina (2011) is aware that indigenous Ubuntu knowledge production and governance are not exempt from oppressive and marginalizing practices, as is the case with the notion of indigenous knowledge itself. According to Dei (2000, p. 113), indigenous knowledges need to develop a critical stance toward “the production and validation of critical knowledge for decolonization purposes.”

During storytelling by Zulus, the audience become active participants who join in the singing and use facial expressions and gestures to coincide with what is taking place in the story. Ubuntu storytelling engages through interactive performance and both the storyteller and listener have specific functions to perform in the making of the story. Performing the story makes it whole in the Ubuntu structure and the repetitive nature of storytelling provides markers of important lessons for the listener.

Mucina (2011, p. 7) uses the Ubuntu structure of storytelling to make “Black people use their stories to talk to other Black people in complex, challenging and sometimes contradicting ways.” The narrative aspect of Mucina’s storytelling “takes the live performative part of storytelling and puts it into written form” so “that the story can be transported across the globe and read by a wider audience” (p. 8). In traditional Ubuntu orality, the storyteller does not analyze the story for the listener but leaves each listener

to analyze the story, knowing that each person will gain something different from it. Achebe (1988, p. 47) says that one of the “consequences of the transition from oral traditions to written forms of literature is the emergence of individual authorship.” That is, the story told by the storyteller no longer belongs to them once they have told it and will be re-composed in some form by the listener to whom it now belongs.

Pūrākau

Pūrākau, usually considered to be Māori myths and legends, was used as a research methodology by Lee (2009) to tell the stories of Māori teachers. Pūrākau is not commonly associated with academic writing or research methodology and has been “reconceptualised as a culturally responsive construct for narrative inquiry into Māori teachers” (Lee, 2009, p. 1). Pūrākau is a traditional form of Māori narrative containing “philosophical thought, epistemological constructs, cultural codes, and worldviews that are fundamental” to Māori identity (Lee, 2009, p. 1). It is a collection of traditional oral narratives, an anthology of literature that remains relevant today and can be “constructed in various forms, contexts and media” to better understand the experiences of Māori in a research context (Lee, 2009, p. 1).

Pūrākau as methodology “draws from and responds to the wider historical, social and political research contexts” and is part of the reclamation process of identifying the colonial influences of research on Māori cultural traditions (Lee, 2009, p. 1). Pūrākau existed for Māori prior to western-based treatment and offers *tangata whaiora* (mental health clients) a culturally specific and valid therapeutic process (Cherrington, 2003). As a kaupapa Māori methodology, it has been used in therapeutic clinical settings with Māori *tangata whaiora* and their *whānau* (family). Using pūrākau as therapy, *tangata whaiora* and their *whānau* have the opportunity to “retell the story using waiata, haka, poetry, drama, sculpting, painting, drawing, storytelling, and/or writing” Cherrington (2003, p. 118).

Talanoa

An oral research method unique to and employed by Pacific peoples is Talanoa (Suaalii-Sauni and Fulu-Aiolupotea, 2014). Talanoa is a “traditional way of developing and revisiting knowledge within Pacific cultures” through what is and was told (Vaka et al., 2016, p. 539; Fonua, 2005). It is an oral research method that enables a cultural synthesizing of participants’ stories in a shared setting (Suaalii-Sauni and Fulu-Aiolupotea, 2014). Talanoa, a Pacific word with similar meanings across many Pacific nations, can simply mean talking but can include cultural ways of talking including why, where, how we talk, and to whom (Vaka et al., 2016). Talanoa is influenced by the “social status, customs and rituals, language, personality and professionalism of the convenor and participants” (Vaka et al., 2016, p. 538). Within the Talanoa, the inclusivity of the participants is balanced with arriving at a consensus within the group. Stories from the heart are explored in a Talanoa, and meanings are unpacked in a friendly and informal approach (Halapua, 2002). Talanoa discussions can be wide-ranging without restrictions on the chosen topic. All perspectives and contributions are welcomed, and the diverse ways in which participants wish to talanoa are accepted.

Talking Circle

Talking Circles are a traditional pattern of intragroup communication specific to Native American communities. Talking Circles have been attributed to Woodland tribes in Midwest United States where it was used as a “form of parliamentary procedure” (Wolf and Rickard, 2003, p. 39). The circle itself is considered sacred and to represent the interconnectedness of all things (people, earth, moon, sun). Talking Circles incorporate symbolic traditions such as burning sage, using eagle feathers, or passing a sacred rock to symbolize a person’s turn to talk. Individuals are given the opportunity to express their thoughts on an issue in both large and small groups by going around the circle and acknowledging the value of each speaker until a collaborative consensus is reached (Sams and Childers, 1990 cited in Wolf and Rickard, 2003). Traditionally, many Native American communities have used the talking circle to bring people together to learn, listen, and teach (Wolf and Rickard, 2003). Talking Circles or Healing Circles are rooted in traditional storytelling and religious ceremonies. These circles have re-emerged among Native Americans to share information, offer support, or solve problems in a group setting and allow for conversations and stories from participants on uncomfortable subjects (Becker et al., 2006).

Yarning

Yarning describes a culture-specific type of conversation among indigenous people in the country that is called Australia (Fredericks et al., 2011). Yarning is more than a light exchange of words and pleasantries in casual conversation (Walker et al., 2014, p. 2). A yarn is both a process and an exchange; it encompasses elements of respect, protocol, and engagement in individuals’ relationships with each other. Yarning establishes relationality and determines accountability and is understood as a means to share stories and listen reflectively to each other (Russell-Mundine, 2007). Yarning has also been differentiated as to whether it is social yarning, therapeutic yarning, collaborative yarning or yarning for more formal research (Bessarab and Ng’andu, 2010).

Halaqah

Halaqah is a spiritual circle-time used by early Muslims and is an integral part of traditional Islamic education. It is a traditional reflexive practice in Islamic cultures with the Qur’an as the reference point. Halaqah is more than a group interview or focus group. It is purely oral with students and teacher sitting in a circle on the floor with the aim of generating group-based narratives (Ahmed, 2014). Halaqah is credited with empowering individuals and communities through a social-justice agenda (Zaimache, 2002).

Digital storytelling

Digital storytelling is a form of storytelling using modern technology. It is the “process of illustrating personal narratives and stories with photographs, artwork, music, voice-overlay, video clips, and text” (Cunsolo Willox et al., 2013, p. 132). Digitalization attempts to avoid the limitations of interview-based narrative research whereby participants’ narratives are processed through the lens of the researcher. The digital process removes the researcher from the data collection stage through to dissemination (Cunsolo Willox et al., 2013). Digital storytelling is an emerging method that has the capability to “preserve and promote indigenous oral wisdom, while engaging community members, developing capacities, and celebrating myriad stories, lived experiences, and lifeworlds” (Cunsolo Willox et al., 2013, p. 128).

Ole Talk as oral research method

Ole Talk—a Caribbean form of communication

The Caribbean is a cultural space marked by cultural diversity, and ethnic and social hybridization and intermixing. Caribbean oral traditions can be found woven into the fabric of Caribbean peoples’ everyday lives, or articulated in highly localized and structured ceremonies. Oral transmission of knowledge is anchored in the ancestral traditions of the Indigenous peoples of the Caribbean as well as the diverse and ethnically mixed groups in the region. In the Caribbean, oral knowledge is transmitted in many forms, ranging from song lyrics to public speaking,¹ or from storytelling to lunch time arguments.

Ole Talk is a culturally specific way of orally transmitting knowledge in Trinidad and Tobago. Ole Talk is found throughout the region albeit with different names,² and takes place across ethnic, class, and geographic boundaries (Fernández, 2020). However, despite their prevalence and familiarity, these practices have been generally overlooked in the literature on Caribbean orality which has focused instead on ancestral storytelling, Creole languages, and music genres like Reggae and Calypso (Cambridge, 2005; Reddie, 1998; Vété-Congolo, 2016).

Ole Talk is a living tradition in Caribbean culture and inheres certain competencies that relate to the Caribbean experience. Some of these include (a) the ability to participate simultaneously in several conversations, (b) managing overlapping talk that is not to be interpreted as interruption, (c) the negotiation of meaning based on humor and performance, (d) interpretation and use of body language and silence to transmit meaning, and (e) the freedom to flow in and out of conversations depending on personal interest.

Ole Talk has frequently been associated with gossip or equated with small talk. However, as has been observed, Ole Talk can be a space where meaning is negotiated, and social discourses are elucidated and contested (Fernández Santana et al., 2019). Significantly, it is also a critical space for collective sense-making, community building and networking (Fernández, 2020). The following section outlines key features of Ole Talk as a Caribbean oral tradition and discusses how Ole talk has been reclaimed as a culturally affirming research method in Caribbean contexts (Fernández, 2020; Nakhid et al., 2020).

Ole Talk in the research environment

In a research context, Ole Talk can be defined as an unstructured oral practice that frequently encompasses storytelling, humor and performance, as well as a multi-layered conversation where participants can engage in multiple dialogues at the same time or none at all. Ole Talk revolves around a research topic that participants have been invited to discuss. Once the researcher has stated the research topic, there are no constraints on the direction that the Ole Talk will take or on the time allowed. The researcher’s role is not that of a moderator, as in a focus group, but participates fully, asking and answering questions and sharing their own experiences (Fernández, 2020).

In education research, Ole Talk offers a valuable reference point for sharing and communicating knowledge about the classroom and the education environment. Ole Talk allows for student research participants from diverse ethnic, socioeconomic, and educational backgrounds to collaboratively make sense of their experiences, relying on shared cultural competencies. Ole Talk occurs naturally in most Caribbean educational environments, both inside and outside the classroom, and can be utilized to gain insights into students’ education experiences.

Ole talk generates a conversational environment in which any topic can be explored from different perspectives depending on what is relevant for each participant or group. The open nature of Ole Talk provides the flexibility for participants to interact and share knowledge on their own terms. For example, if the topic being discussed is not relevant or engaging, participants can choose to be silent or to begin a different conversation alongside the ongoing one. Conversations tend to flow spontaneously with often more than one conversation taking place at the same time and topics can change quickly. Participants frequently talk over each other especially if the ole talkers are engaged and invested in the topic. In most cases, this is not seen as an interruption but as a normal part of the interaction.

In Ole Talk, participants speak (or not) freely and the conversations continue easily, even during heated debates. It is expected and accepted that some people will contribute simply by listening. If participants are uncomfortable with the way in which the conversation is taking place, they can shift the discussion or remove themselves from it altogether. In Ole Talk, the attention given to speakers does not rely on procedure, ritual, or hierarchy, but on the general interest in the topic or conversation. Fernández

¹It is worthwhile to note the Dr. Eric Williams’ University of Woodford Square (Azeez, 1989) where a “speakers’ corner” remains active to this day.

²*dar muela* in Cuba and Dominican Republic; *par* in Jamaica.

(2020) observed that the attention given also depended on the speaker's ability to deliver an entertaining performance or argument, or when the speaker employed humor, teasing, storytelling, or gestures, or modulated the rhythm and tone of the conversation to build momentum. In these cases, listeners become the speaker's audience, and speakers employ any of the communicative strategies listed above to keep them engaged.

Ole Talk features culturally specific humorous practices including good-natured teasing called *relajo*³ or *choteo* in Spanish-speaking Caribbean countries, and *fatigue* in Trinidad and Tobago. The use of humor in Ole Talk for enjoyment and relaxation is not at odds with its significance in knowledge construction, sense-making, and reflection. It is a useful tool in getting research participants to relax, engage, and feel at ease with the research process and other participants. Humor is frequently used to challenge imposed discourses and meanings, not by directly confronting them, but by mocking and transforming them.

Shared humor can bind the group together and becomes a significant coping mechanism when discussing adverse experiences. The shared laughter can be taken as an expression of solidarity. Additionally, when dealing with complex issues, humor enables participants to shape and reshape opinions, intentions, and positions without them being taken as definitive or fixed. This creates an environment of permissibility in which diverse opinions on controversial issues can be explored at ease.

Ole Talk inheres important similarities with indigenous conversational methods which, as discussed by Kovach (2010).

... comprise a specific way of knowing based upon the oral tradition of sharing knowledge. It is akin to what different Indigenous researchers, the world over, identify as storytelling, yarning, talk story, re-storying, re-membling (p. 124).

With localized conversational methods such as Ole Talk, relationships are of vital importance. Through collaborative storytelling, both the researcher and the knowledge holder become engaged in a shared process of knowledge construction and the relationship builds and deepens as stories are shared.

Kovach (2010) has noted that, in many indigenous conversational methods, protocol is of high importance to ensure that activities are carried out in a manner that reflects tribal traditions. Although there are cultural expectations around Ole Talk, this mode of interaction is not reliant on a fixed format. The utilization of the cultural competencies of Ole Talk such as participating in several dialogs at once, using humor meaningfully, and the use of silence for communication is largely unprescribed and undirected. Additionally, the habitus that is embodied in Ole Talk is not particular to a single ethnic group but has emerged from the cultural integration of the many peoples of the Caribbean (Glissant, 1989).

Ole Talk is seen as a culturally affirming research method in research by and with Caribbean people as the strategies for knowledge construction emerge from Caribbean experiences and cultures. Researchers and participants are equally involved in the process of sense-making, are familiar with the underlying codes and dynamics of Ole talk, and share the power to shape knowledge. This differs from research approaches where the researcher has primary access to the structures that shape the knowledge (e.g. questions in an interview, time keeping in a group discussion, moderation in a focus group). The oral practices of Ole Talk, emerging from the practical and living realities of Caribbean communities, enable research that affirms the localized ways that these communities share knowledge and in which the results of the research are more likely to be effectively aligned with their own understandings and current lives.

Ole Talk in practice

The characteristics of Ole Talk, described above, frame the process of knowledge construction. When Ole Talk is used in research, other aspects of the research process need to take into account the fluid, unstructured and dynamic nature of Ole talk. The following section suggests ways in which certain steps of the research process could be carried out when using Ole Talk. These suggestions are not limited to Ole Talk and can be used with other oral traditions with the expectation that the integrity of their unique cultural groundings will be maintained.

Recording Ole Talk

Ole Talk continues as people move around from one group to the other, or gravitate toward shared food. This necessitates having more than one recording device in order to capture the many conversations. The use of multiple recorders, located in strategic places in the setting allows for the recording of multiple conversation groupings, and for people to shift between groups. Videos can be used, with permission, to capture non-verbal interactions in a way that is minimally intrusive. Recorder-free areas can be created to enable participants to be off record if they wish.

Transcribing Ole Talk

Ole Talk data captured in multiple recordings are likely to be complex and multi-layered. Transcription needs to capture this complexity to enable an accurate analysis of the knowledge shared. When transcribing Ole Talk, context needs to be captured as well as discourse. This includes prosodic information (intonation, gestures, and stress patterns), conversation overlap, humor,

³*Relajo* does not have an exact English equivalent, but it refers to a state of suspension of all seriousness, usually involving the use of well-intended back and forth mockery, double meaning, and humor. It denotes a mode of joking around and not taking anything seriously, and usually involves well-meaning teasing with shared laughter as a typical outcome. For example, a phrase like: “*Déjense de relajo!*” can be translated as “Stop joking around!”

Table 1 Examples of the use of oral traditions in education research.

Oral research method	Research studies in education	Focus of studies
Storytelling	Gallagher, K.M., 2011. In search of a theoretical basis for storytelling in education research: story as method. <i>Int. J. Res. Method Educ.</i> 34(1), 49–61. Collins, F., 1999. The use of traditional storytelling in education to the learning of literacy skills. <i>Early Child Dev. Care</i> 152(1), 77–108.	Utilizing the works of Hannah Arendt and Bertold Brecht, two theorists of great storytelling capability, the author considers how their methodological thinking might be productively imported. Investigates what storytelling offers to the formal education of primary age children.
Ole Talk	Ferguson, S., (forthcoming). <i>The Role of Community Environments on First-Generation Jamaican University Students' Persistence in Higher Education</i> . [Doctoral Dissertation, the University of Denver].	Employing ole talk in online (liming online) to understand the role of community environments for first-generation Jamaican university students in higher education journey.
Ubuntu	Quan-Baffour, K.P., Romm, N.R., 2014. Ubuntu-inspired training of adult literacy teachers as a route to generating “community” enterprises. <i>J. Lit. Res.</i> 46(4), 455–474. Mukuni, J., Tlou, J., 2018. The place of Ubuntu in global education. In: <i>Cases on Global Competencies for Educational Diplomacy in International Settings</i> . IGI Global, pp. 223–248.	The use of Ubuntu in the various learning settings in the training of adult literacy teachers. How global education can benefit from Ubuntu, and how Ubuntu aligns with the global competencies articulated in the Global Competence Matrix.
Pūrākau	Cliffe-Tautari, T., 2020. Using Purakau as a pedagogical strategy to explore Maori cultural identities. <i>Set: Res. Inf. Teach.</i> 1, 12–18.	Unpacks how pūrākau as a pedagogical strategy enables Māori learners to explore their own perceptions about being Māori.
Talanoa	Latu, M., 2009. <i>Talanoa: A Contribution to the Teaching and Learning of Tongan Primary School Children in New Zealand</i> (Doctoral Dissertation, Auckland University of Technology). Baice, T., Lealaiauloto, B., Meiklejohn-Whiu, S., Fonua, S.M., Allen, J.M., Matapo, J., et al., 2021. Responding to the call: talanoa, va-vā, early career network and enabling academic pathways at a university in New Zealand. <i>High. Educ. Res. Dev.</i> 40(1), 75–89.	Using Talanoa to explore alternative approaches to teaching and learning pedagogies of Tongan children in New Zealand. Using Talanoa to privilege the worldviews and stories of the under-representation of Pacific/Pasifika academics in universities across Aotearoa New Zealand.
Talking Circles	Hanson, A., Danyluk, P., 2022. Talking circles as indigenous pedagogy in online learning. <i>Teach. Teach. Educ.</i> 115, 103715. Schumacher, A., 2014. Talking circles for adolescent girls in an urban high school: a restorative practices program for building friendships and developing emotional literacy skills. <i>Sage Open</i> 4(4), 2158244014554204.	Using talking circles as indigenous pedagogy in online education for preservice teachers. The use of talking circles to investigate peers helping peers in an urban high school.
Yarning	Gruppette, M., Southgate, E., Ober, R., Cameron, L., John, F., Thunig, A., et al., 2018. Yarning the way: the role of indigenous paraprofessionals in guiding the post-school educational pathways of aboriginal and Torres Strait Islander youth. Flückiger, B., Diamond, P., Jones, W., 2012. Yarning space: leading literacy learning through family–school partnerships. <i>Australas. J. Early Child.</i> 37(3), 53–60.	Examining the role of indigenous education paraprofessionals in facilitating post-school education options and access for indigenous young people through yarning. The use of yarning to look at effective partnerships between parents, teachers and the community to improve young indigenous Australians’ participation in early childhood education and their literacy development.
Halaqah	Shirin, H.B., Islam, A.A., Islam, M.S., 2017. Development and validation of the study circle model in higher education: the application of structural equation modeling. <i>MOJEM</i> 2(3), 18–32. Munadia, A., 2016. <i>The Enhancement of Critical Thinking Using Halaqah Method Among Students of Dayah in Dayah Mudi Mesjid Raya Salamanga, Aceh</i> (Master’s Thesis, Gombak, Selangor: International Islamic University Malaysia, 2016).	The study circle (Halaqah) program to disseminate the knowledge and skills for overcoming the drawbacks and challenges among students, in one of the Islamic universities in Malaysia. This study investigated the enhancement of critical thinking skills using halaqah method among Dayah students at Dayah Mudi Mesjid Raya Samalanga Aceh, Indonesia. It examined the teachers’ perceptions and practices of critical thinking in the classroom.
Digital storytelling	Van Gils, F., 2005. Potential applications of digital storytelling in education. In: <i>3rd Twente Student Conference on IT</i> (vol. 7, No. 7). University of Twente, Faculty of Electrical Engineering, Mathematics and Computer Science Enschede. Alismail, H.A., 2015. Integrate digital storytelling in education. <i>J. Educ. Pract.</i> 6(9), 126–129.	Digital storytelling as offering a new way of to educate people. Explores how digital storytelling can be an effective tool for both teachers and students in order to support learning and skills.

and laughter. It is important to structure the transcribed material to the aims of the particular study so that the relevant information is emphasized. For example, transcription tables with columns can note when limers talk over each other or when they laugh. Different shading can be used to distinguish one conversation from another when multiple groups are talking at the same time (Table 1).

Talking over each other	Sam	You go now, scrap your elbow, your mother then come, take you up, rubs the alcohol, makes you holler ...
	Nina	And then cut your arse
Talking over each other	Sam	Are you going outside again? Sometimes I do get your point, people go too far, I agree.
	Nina	Tough love, tough love
	Helen	That's why you so?
Laughter	Renee	That's why I'm so tough
	Helen	I think you ... there is a difference between being ... articulate ... I think you are sensitive, I think you are. I know you are.

Analyzing and reporting Ole Talk

When Ole Talk is used as the primary source of data, it is recommended that data analysis and the writing of the report be carried out simultaneously. This allows the researcher to adapt the structure of the report to the narratives and ideas emerging from the Ole Talk. When writing up the study's findings, the researcher can thus go back to the recordings to contextualize participants' conversations and to make sense of the situation in which the conversation emerged, the reaction of other participants, and other relevant behaviors such as tone, use of humor, movement and position, and talking over each other.

Representing the rich interactional practices of Ole Talk in a written text requires simplifying the data. However, to preserve some of its complexity, writing strategies can be developed to include nonverbal and contextual information, and to maintain the integrity of participants' narratives. Oftentimes in academic text, textual quotes from participants are provided without description of the context in which they were said. In an Ole Talk interaction, the meaning of a phrase can change dramatically depending on tone, body language and context. Therefore, it is recommended to incorporate sufficient description to capture features such as nonverbal communication surrounding discourse, the position and movement of participants, the tone of their voices, and their gestures. Below is an example of how this can be done, with the description of context and non-verbal communication in italics.

Everyone around the table had been sharing their migrant journey. Gabe went back to when his parents arrived in the UK from the Caribbean.

"Okay, so in the sixties" Gabe started locating his narrative, "big, big, big mass migration from the Caribbean. They were invited, and said that everything was going to be ... they were gonna get a job, and blah, blah, blah and when they go over there ..." Gabe shook his head and rolled his eyes, looking at Anand.

"They were invited" confirmed Anand, nodding.

"They lied to them" Derek added, sadly.

MIRIAM'S LIME. OLE TALK FRAGMENT 6.

Additionally, Ole Talk fragments quoted in the text can be numbered (see above) and referenced throughout the text to enable the researcher and readers to go back and forth connecting different parts of participants' narratives.

Application of Ole Talk in research

Ole Talk is being used increasingly in research in Caribbean contexts and with Caribbean peoples. Liming and ole talk, developed as Liming Methodology, was employed by Fernandez (2020) to investigate how Caribbean Islanders living in Aotearoa articulated a Caribbean identity. Kerrigan (2016)'s study of "small goal" football in Trinidad relied on Ole Talk to understand the relationship between sport and masculinities in the country.

In ongoing research, Ferguson's (forthcoming) study uses online (liming online) to understand the role of community environments for first-generation Jamaican university students on their higher education journey, specifically focusing on students/graduates from under-resourced and under-served communities in Jamaica. Chapman (forthcoming) uses liming and ole talk to investigate how colonial policing systems have shaped the current paramilitary policing of black and brown bodies in Trinidad and Tobago.

Conclusion

In research, oral traditions have intrinsic value to the community where research is unfolding, and this value is not related to their compliance with or contestation of foreign paradigms. Importantly, oral traditions operate as affirming research methodologies when those who share knowledge are centered as agents in the research process in an intersubjective relationship with those who may hold a formal role as researchers.

This shift from traditional research hierarchies requires intentionality. Oral traditions are intrinsically fluid and grounded in the lived experience of the people who embody them. If this process of re-centering participants and their experience in the research

process is not intentionally ensured, mainstream research positionings can take over leading to the corruption and disenfranchisement of oral traditions to exploit the knowledges of communities. Thus, a determining factor in identifying oral traditions as affirming methodologies is their ability to reclaim and center local and indigenous ways of constructing and sharing knowledge.

Oral traditions are as diverse as the cultures and communities in which they are located. Storytelling is a profoundly important cultural resource in many Indigenous societies. The way in which stories are shared varies among the many peoples that use storytelling. For example, Ole Talk, Pūrākau, Talking/Sharing circles, Yarning, Talanoa, Halaqah, or Ubuntu or Digital storytelling enables the sharing of stories with varying degrees of structuration, formats, and modes of participation.

Oral traditions are central to communities that are diverse and highly transient such as Caribbean communities. Oral traditions keep people connected and make knowledge accessible to people in their day-to-day life. With research involving Indigenous, Black, and People of color education communities, oral traditions such as Ole Talk create a space for authentic engagement where participants can talk to and over each other, provide space for humor and reflection, and listen to histories that hurt and stories that heal.

In education research, the use of oral traditions facilitates a more authentic and participatory space for communities that rely on orality to explore their own learning processes (inside and outside formal learning institutions) as well as critique the factors that shape their educational outcomes. Research in education can use oral traditions within an Affirming Methodologies framework to elicit conversations about how learning takes place, in an environment that is safe, strengths-based and encourages participants to build knowledge that centers, and is connected authentically to who they are and how they see the world.

Glossary

- Connotation** The extended or acquired meanings of a sign
- Denotation** The referential or intentional meaning of a sign
- Markedness theory** The theory which posits that one of the two elements in an opposition is the default (unmarked) form and the other the marked form (the one that stands out)
- Opposition** A relation that keeps signs distinct from each other through minimal contrasts (*night* vs. *day*)
- Paradigmatic structure** Any aspect of signs that keeps them distinct
- Semantic differential** Technique for identifying connotative meanings based on seven-point scales
- Semiosis** The process of producing and understanding signs
- Signification** The process of using signs for various psychological and social-cultural reasons
- Signified** The conceptual part of the sign; what the sign encodes and refers to
- Signifier** The physical part of a sign; also known as form
- Syntagmatic structure** The combinatory structure of signs (how they have been constructed)

Introduction

As the discipline studying and documenting signs, sign behavior, sign creation, and sign functions, semiotics is an ideal tool for conducting qualitative research in the cognitive and social sciences, since human cognition, behavior, and even perception is guided by sign structures, if not structured by them. A sign is defined as any physical form that stands for something other than itself in some specific context. A V-shape made with the raised index and third fingers is a perfect example of a sign, since it does not stand for raised fingers but for a series of referents ranging from the number two to abstract notions such as peace and victory. It all depends on who uses it and in what context it is used.

Today, semiotics is used mainly as a methodological tool to study such sign-based phenomena as body language, visual communication, social media, advertising, narratives, material culture (clothing, cuisine, etc.), rituals, the study of digital forms and systems—in a phrase, anything that is informed by sign-based activities or behavior. One of its modern-day founders, the Swiss philologist Ferdinand de Saussure (1857–1913), defined it as the science concerned with “the role of signs as part of social life” and “the laws governing them” (de Saussure, 1916/1958, p. 15).

A sign (a word, a visual image, a hand gesture, and so on) selects what is considered by people at specific moments in time as important to be known and recalled from the infinite variety of things that are in the world. It imprints knowledge into structured forms which filter out extraneous information. Although we create new signs to help us gain new knowledge and modify previous knowledge, by and large, we literally let our signs “do the thinking” for us, once we have acquired them in context. We are born into an already-fixed system of signs that will largely determine how we view the world around us and within us. This system sustains psychological life (based on nongenetic information) through expressive, communicative, and representational activities, forming a kind of symbiotic partnership with the biosphere to regulate human behavior and to shape cultural and social evolution. But it is not a deterministic partnership. Humans have the capacity to redesign aspects of semiotic life and thus completely refashion the sign structures they have created.

This chapter looks at the discipline of semiotics, starting with a historical synopsis of its origins and major developments. It then describes the two major theories of the sign, by Ferdinand de Saussure and Charles Sanders Peirce, which still form the foundation

of semiotic theory and practice. Saussure saw the sign as a binary structure—its physical form and its meaning—while Peirce saw it as a triadic structure—its physical form, its meaning, and its changing interpretation. The chapter then looks at Peirce's main categories of sign classification, the distinction between denotative and connotative meaning, the use of the semantic differential to evaluate the latter kind of meaning, the notions of oppositional structure and markedness, and their critique by the movement called post-structuralism. Finally, the applications and implications of semiotics to qualitative research are discussed, including an example of how it has been applied in the area of education.

Defining and classifying signs

The initial task of any science is to define its objects of investigation. This is also the case with semiotics, whose object of interest is *signs*—words, symbols, gestures, and so on, along with their social functions, their interpretations, and how they encode knowledge in specific ways. The first technical definition of the sign goes back to the ancient world, starting with the Greek physician Hippocrates (c. 460–370 BCE), who argued that the particular physical form that a bodily symptom takes – a *semeion* (mark) – constitutes a vital clue for finding its etiological source. He called the method of diagnosis *semeiotiké* (semeiotics), laying the foundations for the diagnosis, treatment, and prevention of disease, taking into account not only the biological sources of the physical symptomatic signs themselves, but also what they meant to patients and to the culture in which they were reared. After Hippocrates, the question arose at some point as to whether or not there was any connection between natural signs, such as symptoms, and conventional ones, such as words—a connection first discussed by the Stoics around 300 BCE, who argued that conventional signs were reflections of natural ones.

In the early medieval period, philosophers started referring to signs as being either natural (produced by the body or nature) or conventional (invented by humans). It was the early Christian church father, St. Augustine of Hippo (354–430 CE), who put forth an early typology of signs in his masterwork *De doctrina christiana* (Augustine, 1887), in which he describes natural signs (*signa naturalia*) as forms lacking intentionality and conventional ones (*signa data*) as forms produced by human intentions. The former include not only symptoms, but also plant coloration, animal signals, and the like; the latter include words, gestures and the various symbols that humans invent to serve their psychological, social, and communicative needs (Deely, 2001, pp. 24–56). The distinguishing feature of natural signs is that they have no human intent behind them. They occur naturally, outside of human volition. However, humans have an innate desire to interpret them in their own way. To do so, they invent conventional signs, which are products of intentions and needs.

St. Augustine's views lay largely unknown until the eleventh century, when interest in signs was rekindled by Persian scholars, who brought the works of Plato, Aristotle, and other Greek thinkers to medieval Europe. The result was the movement known as *Scholasticism*. Using Aristotelian philosophy as their model, the Scholastics asserted that signs allowed humans to capture truths, and thus to know the world through them. But within this movement there were some—the so-called *nominalists*—who argued that “truth” was a matter of subjective opinion and that signs captured, at best, only illusory and highly variable human versions of it. John Duns Scotus (c. 1265–1308) and William of Ockham (c. 1285–1349), for instance, stressed that signs only referred to other signs, rather than to actual things. The Scholastic theologian St. Thomas Aquinas (1225–1274) countered, however, that signs referred to real things, since they were derived from sense impressions. He also asserted that sacred signs revealed truths that were beyond rational comprehension and, therefore, had to be accepted on faith. In the same era, the English philosopher and scientist Roger Bacon (c. 1214–1292) developed one of the first comprehensive typologies of signs, claiming that, without a firm understanding of the role of signs in human understanding, discussing what truth is or is not would end up being a trivial matter. Bacon's proposal to study signs separately elicited little or no interest until 1690, when British philosopher John Locke (1632–1704) revived it in his *Essay Concerning Humane Understanding* (Locke, 1690). Locke used the term *semeiotics* in reference to a set of principles for examining signs and their meanings, not in reference to a distinct discipline or method of inquiry. It is not clear where Locke got the idea to use this Hippocratic term. The same term was used two decades earlier in 1670 by the English physician Henry Stubbe (1632–1676) to designate the interpretation of signs within medicine.

The idea of fashioning an autonomous science of sign study, however, did not crystallize until the nineteenth-century Swiss philologist, Ferdinand de Saussure (de Saussure and Baskin, 1916), put such a proposal forward, which he called *sémiologie* (semi-ology). As the following citation (de Saussure and Baskin, 1916, pp. 15–16) shows, Saussure suggested that the main goal of semi-ology (should it ever come into being) was to understand the social function of signs, as a branch of psychology, putting linguistics as itself a branch of semiology:

It is possible to conceive of a science which studies the role of signs as part of social life. It would form part of social psychology, and hence of general psychology. We shall call it *semiologie* (from the Greek *semeion*, “sign”). It would investigate the nature of signs and the laws governing them. Since it does not yet exist, one cannot say for certain that it will exist. But it has a right to exist, a place ready for it in advance. Linguistics is only one branch of this general science. The laws which semiology will discover will be laws applicable in linguistics, and linguistics will thus be assigned to a clearly defined place in the field of human knowledge.

Saussure saw the sign as a binary structure composed of two interrelated dimensions—a physical component (the sign itself) and a conceptual component (what it refers to and brings to mind). Saussure termed the former part, such as the phonemes that make

up the word *cat*, the *signifier*, and the concept or mental image that the sign elicits (the feline animal), the *signified* (literally meaning “that which is signified by the sign”). Saussure claimed, moreover, that there is no necessary sensory or experiential connection between the signifier and the signified. So, the actual phonemic structure of the word *cat* is an arbitrary one, with no perceivable linkage between the sounds that make up the word and the animal itself—that is, the word *cat* is not constructed to simulate or imitate the sounds a cat makes, as in onomatopoeic constructions. Any other signifier would have sufficed—as long as it conformed to the laws of word formation in the language (that is, the rules for combining phonemes to form legitimate words). While this aspect of Saussurean sign theory is disputed by semioticians today, the main idea behind it is still a relevant one—namely that the two parts of a sign imply each other conceptually. So, when we use or hear a word such as *tree* (the signifier), an image of the signified (a certain type of plant) crops up concomitantly in our minds—if we know English of course—even if a real tree is not present for us to observe. Now, if we do come across a tree in reality, then the word we use for it (*tree*) also comes to mind. In other words, when the word *tree* is used, an image of the arboreal plant occurs in the brain; vice versa when we see this arboreal plant the word *tree* is suggested concomitantly in the brain. This is why Saussure called word signifiers sound images and their signifieds mental images. The two are inextricably intertwined—one implying the other. Needless to say, wherever “trees” are not part of a culture’s reality (such as, for example, in nomadic desert cultures), no signifier for them is required in the first place (since there is no signified to be encoded).

The first modern-day technical classification of signs is due to the American pragmatist philosopher Charles S. Peirce (1839–1914), who identified 66 species of signs in total. Some of these provide detail as to how signs function cognitively. For example, as its name implies, a *qualisign* is a form that draws attention to some quality of its referent (the object it represents). In language, an adjective is a *qualisign* since it draws attention to the qualities (color, shape, size, etc.) of nouns. In other sign systems, *qualisigns* include colors (painting), harmonies and tones (music), etc. A *sinsign* is a form used to single out a particular object – a pointing finger and the words *here* and *there* are examples of *sinsigns*. A *legisign* is a form that designates something by convention (literally by law). *Legisigns* include symbols, emblems, such as those used on flags, and various other forms that are used according to specific social rules or conventions. However, there are three fundamental types of signs identified by Peirce that are now part and parcel of every semiotician’s methodological toolkit – *icons*, *indexes*, and *symbols*. Signs originating in the perception of some property in a referent are icons. So, iconic signs stand for their referents by resemblance, imitation, simulation, or emulation. Portraits are icons of human faces (and what they mean); onomatopoeic words are icons of sounds made by certain objects or actions (drip, bang, etc.); and so on. The meanings of icons can generally be figured out even by those who are not a part of the culture that use them. Signs that relate referents, sign users, and even other sign forms in some way are defined as indexes. The pointing finger is a perfect example of an index. When we point to something, we are in fact relating it to our location as pointers. If it is close by, we refer to it as *near* or *here*. If not, we refer to it as *far* or *there*. Finally, signs that stand for referents in historically based or conventional ways are symbols. The V-figure standing for peace has symbolic valence, that is, it is interpreted conventionally for peace as a result of some historically or culturally based event.

Signs and meaning

Semiotic inquiry is guided generally by two fundamental models of the sign – Saussurean and Peircean. As discussed briefly above, Saussure saw the sign as a binary form with two components –the signifier and the signified (de Saussure and Baskin, 1916, p. 101)—which are connected to each other in an arbitrary way. Peirce saw some signs as originating instead in perceptual modeling tendencies (icons). In contrast to Saussure, he claimed that iconicity is a basic tendency in sign-creation and sign-interpretation (which he called *semiosis*). Peirce put forward a triadic model of the sign – a structure consisting of the actual physical sign form, called the *representamen*, the thing to which it refers, termed the *object*, and the meanings that it elicits in real-world situations, called the *interpretant* (Peirce, 1931, vol. 2, pp. 247–248, 307). The interpretant is itself a derived mental sign, because it entails the further production of meanings arising from the context in which the sign is used. In our culture, a cat is considered to be a domestic companion, among other things; in others, it is viewed primarily as a sacred animal; and in some others, it is considered to be a killer of rodents. Thus, while the sign refers to virtually the same mammal in different cultural contexts (no matter what name is used), its interpretant varies considerably. Thus, while the sign *refers* to virtually the same mammal in different cultures (no matter what linguistic name is used), its interpretant varies considerably, constituting a source of supplementary semiosis.

Unlike Saussure, Peirce viewed conventional signs (such as words) as originating, by and large, in the attempt to reproduce perceivable properties in their objects. Therefore, the Peircean sign is a *motivated* (not *arbitrary*) structure, whose construction is guided originally by some sensory, affective, or historical impulse. Peirce termed this a *firstness* dimension, defined as the tendency to construct or understand signs—*first*—as simulations of some perceived property of their objects or as related by resemblance to other objects or signs. He called the actual process, *iconicity*. An obvious example of an iconic sign is the word *splash*, whose phonemic structure was clearly modeled to imitate the sound made by something striking or falling into a liquid. Saussure did admit that some signs were fashioned in this onomatopoeic way. But he maintained that this was the exception, not the rule. However, as Peirce suggested, our *first* tendency in semiosis is to construct signs iconically, even though we may no longer be aware of it. Many words possess a latent sound-imitative quality built right into their structure. Consider the word *duck*. The sound combination that makes it up is, to be sure, one of an infinite number of assemblages that can be envisioned in English. But the final/k/of that word hints at the kind of sound a “duck” is perceived to make, referenced much more directly in the word *quack*. This type of “iconic modeling” is intrinsic to sign creation, even if it is not always obvious. Since iconic signs are fashioned in specific historical

contexts, their physical forms are not universal, as might be expected. Peirce used the term *hypoicon* to acknowledge this context-based dimension of firstness. Nevertheless, because it is an experientially-based process the referent can be figured out even by those who are not part of the culture, if they are told how a sign simulates, resembles, or substitutes it. Thus, if someone who does not speak English is told that the expression *cock-a-doodle-do* stands for the sound a rooster is perceived to make, then that person would have little difficulty imagining the resemblance between the expression and its referent. Peirce called the tendency of relating referents and sign-users in some way, *secondness*. This engenders indexical signs, such as the pointing finger or words such as *here*, *there*, *up*, *down*, and so on. Finally, Pierce claimed that there exists a *thirdness* dimension in sign construction, which consists in learning and using the conventional signs (symbols) developed in specific cultural contexts. The Union Jack stands for Great Britain—it is interpreted historically, conventionally, and emotionally as a sign of nationhood.

A major problem for semiotics is to determine what meaning is and how it manifests itself through signs. To avoid ambiguity, the terms *semiosis* and *signification* are used by semioticians. The former, as mentioned, refers to the psychological process itself of producing and recognizing specific forms as signs (Fisch, 1978, pp. 32, 41); the latter refers to the mental images that crop up in the brain when a sign is used. Signification involves two main meaning-making processes – *reference* and *sense*. Reference is the process itself of identifying what the sign form captures; sense is what that form elicits psychologically, historically, and socially. Signs (such as words) may refer to the same (or similar) things, known as referents, but they have different senses. For example, the “long-eared, short-tailed, burrowing mammal of the family Leporidae” can be called *rabbit* or *hare* in English. Both words refer essentially to the same kind of mammal. However, there is a difference of sense between the two words – *hare* is the more appropriate term for describing the mammal if it is larger, has longer ears and legs, and does not burrow. Another difference is that a rabbit is often perceived to be a pet, while a hare is unlikely to be perceived as such (Danesi, 2007, p. 34).

For many semioticians, the terms *denotation* and *connotation* are preferred to reference and sense. Consider, again, the word *cat*. The word elicits an image of a “creature with four legs, whiskers, retractile claws”, etc. This is its denotative meaning. As this shows, the function of denotation is referential – that is, it allows users of the sign to determine if something real or imaginary under consideration is a cat or not. Denotative meaning thus divides the world of reference into “yes–no” domains – something is either a cat or it is not. All other meanings of the word are connotative – “He’s a real cool cat;” “She let the cat out of the bag;” and so on. These meanings are products of the historical associations forged between cats and socially significant concepts or processes. Connotation thus connects the world of reference to larger historical processes. Connotation is not an option, as some traditional philosophical and linguistic theories of meaning continue to sustain to this day; it is something we are inclined to extract from a sign. The numbers 7 and 13 have specific denotative meanings – each digit stands for a specific quantity of things. However, in various cultures, both invariably reverberate with connotative meanings such as fortune, destiny, mysticism, and so on. In 1957, the psychologists Osgood, Suci, and Tannenbaum showed how connotative meaning is built into everyday concepts by using a technique that they called the semantic differential. This consists in asking a series of evaluative questions to subjects about a particular concept – Is X good or bad? Should Y be weak or strong? etc. – which they are then told to rate on seven-point scales. The ratings are collected and analyzed statistically in order to sift out any general pattern that they might bear. Suppose that subjects are asked to rate the concept “ideal American president” in terms of the following scales: Should the president be: (1) Young or old? (2) Practical or idealistic? (3) Modern or traditional? (4) Male or female? and so on. A subject who feels that the president should be more youngish than oldish would place a mark toward the young end of the first scale; one who feels that a president should be traditional, would place a mark toward the traditional end of the scale; and so on. Research using the semantic differential has shown that connotation is invariably culture specific.

Research utilizing the semantic differential has also shown that the range of connotative variations is not a matter of pure subjectivity, but forms a socially-based pattern. Younger people may tend to rate the “ideal parent” as being flexible, older ones as “stern.” But this will vary according to culture, and in fact the semantic differential will flesh out the culturally-significant connotations of specific concepts. In other words, the connotations of concepts are constrained by psychological and cultural factors. A common critique of the technique, however, is that the scales used (*practical-versus-idealistic*, *flexible-versus-stern*, etc.) are themselves artifacts, utilized by the researchers to unconsciously guide subject choices along a certain path that is itself culturally-biased. In other words, they show what analysts want to show. But even if the scales are determined in advance, the results obtained may be unexpected ones and thus the whole technique would be legitimate as a form of randomized experimentation. In effect, the semantic differential remains a valid investigative tool into the nature of connotation, since it allows us to flesh out what something means in cultural terms (within limits).

Structure

In order to extract meaning from a sign, sign system, or sign assemblage (text), one must be able to recognize it as such in the first place. This means that it must have structure. Specifically, a sign (or sign assemblage such as a text) is recognizable as such if: (1) it is physically distinctive and (2) it is organized in a patterned way. The former implies *paradigmatic* and the latter *syntagmatic* structure. The phonic difference between *cat* and *rat*, for example, is a paradigmatic feature, allowing the native speaker to perceive the difference as a cue to meaning differentiation. Paradigmatic structure, as this simple example shows, involves some form of meaning-bearing differentiation in the physical makeup of a sign. In music, major and minor chords of the same key are perceivable as significantly different on account of a half-tone difference in the middle note of the chord; raising the index and middle fingers in a vertical orientation can mean victory, or peace (among other meanings), but aiming the same two fingers in a horizontal

way at someone would be interpreted instead as a threat; and so on. Now, the way in which the sounds of the word *cat* are put together is a further cue as to its meaning. Simply stated, the sounds of the word have been put together in line with English syllable structure. This is an example of syntagmatic structure. In music, a melody is recognizable as such only if the notes follow each other in a certain way (e.g., according to the rules of harmony); writing words in English involves putting the letters in a left-to-right form to stand for phonemes (more or less); and so on. In essence, a sign is perceivable as a meaning-bearing form if it bears paradigmatic (differential) and syntagmatic (combinatorial) structure in tandem.

Another main tenet of semiotics is that signs can vary in structural size, that is, in actual physical form. A sign can thus be something small, such as two fingers raised in a V-form; or it can be something much larger, such as a mathematical equation or a narrative. The interpretation of the sign is in all cases holistic, not discrete (decoded in terms of its constituent parts). If asked what $c^2 = a^2 + b^2$ means, a mathematician would say that it stands for the Pythagorean theorem, not for specific digits captured by the letters used (even if this is also true). If we ask someone who has just read a novel what it was all about, we would receive an answer that reveals a perception of the novel as a form containing a singular (holistic) message or purpose. The larger signs constructed by combining smaller ones (such as words in the novel) are called *texts* and the meanings we extract from them are called *messages*, rather than just signifieds. The term *text* embraces such things as conversations, letters, speeches, poems, myths, novels, television programs, paintings, fashion styles, scientific theories, mathematical equations, musical compositions, and so on. Texts are composite structures (signs made up of smaller signs) that are not interpreted in terms of their constituent parts, but holistically as single meaning-bearing structures.

Texts function primarily as representation devices, intended to relate, depict, portray, or reproduce something perceived, sensed, imagined, or felt as requiring signification by means of a complex (combinatorial) form. This implies knowledge of how signs cohere into systems or *codes*. To enter into a conversation, for example, one would need to know the language code involved – the system of sounds, words, syntactic rules, etc. that allows for conversation to occur. Language, dress, music, and gesture, among many other things, are examples of codes. These can be defined, more formally, as systems of signs that can be used over and over to encode and decode texts. There are many kinds of codes. For example, intellectual codes contain signs in them (numbers, words, symbols, etc.) that allow for representational activities of a logical, mathematical, scientific, or philosophical nature. Social codes (dress, gender, food, space, etc.) contain sign structures for making messages about oneself in socially appropriate ways and for regulating interpersonal activities. Food codes underlie how people interpret certain foods as signifiers of various rituals, meanings, etc. It is important to note that once a text is constructed, it takes on its own paradigmatic and syntagmatic properties – that is, it is differentiable from other texts in terms of the kinds of signs that constitute it (verbal, pictorial, etc.), and it is the result of specific syntagmatic properties associated with the code or codes utilized to construct it (language, narrative, and so on). A semiotic *code* can be defined as the meaning-assigning system that inheres between signs organized in a certain way, with a certain function, or bearing specific information. Technically, the definition of the sign is “something that stands for something else in a certain way.” A code is the term for the “stands for” relation, which is completed with “in a certain way.”

Some codes are codes within codes (or subcodes); others are meta-codes, that is “larger codes” that encompass these subcodes—although this distinction is rarely made in semiotics for practical purposes—it is a theoretical distinction. So, the term *code* can refer to a meta-code or a subcode, with each term used distinctively if necessary. An example of a larger all-encompassing meta-code is language. Each level within it has coded structure. For example, knowledge of words entails knowledge of (1) how they are formed phonemically; (2) how they cluster into phrases and sentences; (3) how they are inflected; which words (known as *function words*) can be used to relate the other words in a sentence to each other; and (4) how they bear denotative and connotative meanings when used in specific forms. Saussure called the language meta-code, *langue*, and the ways in which it is used or expressed, *parole*—rendered generically in English as *language* and *speech* respectively. Language is a mental code. Speech is how language is delivered, involving the intentional use of the organs of the vocal apparatus—the tongue, the teeth, the epiglottis, etc.—to articulate sounds and words. Language can also be delivered or expressed through other physical modes—writing, gesture, and so on. One can have language without speech (as do individuals with impaired vocal organs), because it exists in the mind. But one cannot have speech without language, because speech depends on the language code.

To identify forms as meaning-bearing structures, Saussure introduced the notion of *différence*. This was expanded by the so-called Prague Circle of linguists in the 1920s and 1930s into the technique known as opposition, which has been used across disciplines, from psychology to linguistics. For the sake of historical accuracy, it should be mentioned that this notion is, implicitly, an ancient one, being characteristic of myths (good vs. evil, youth vs. old age, etc.). The Prague Circle linguist Trubetzkoy (1936, 1968), however, was the first to apply it formally to the study of the structure of language. According to psychologist Ogden (1932, p. 18), an early promoter of opposition theory, opposition had general applicability because it offered “a new method of approach not only in the case of all those words which can best be defined in terms of their opposites, or of the oppositional scale on which they appear, but also to any word.” In the 1930s and 1940s, semioticians started noticing that oppositional structure was not confined to language. It cropped up in the analysis of nonverbal systems and codes as well – in mathematics, for example, fundamental oppositions include positive versus negative, odd versus even, and prime versus composite; in music, they include major versus minor and consonant versus dissonant; and so on.

The Prague Circle linguists also argued that there were orders of oppositions that went beyond the purely binary. In mathematics, for example, the addition-versus-subtraction opposition is a basic or first-order one, while the multiplication-versus-division opposition is a derived or second-order one – since multiplication is repeated addition and division repeated subtraction. French semiotician Algirdas J. Greimas later introduced the notion of the semiotic square to connect sets of oppositions (Greimas, 1987). Given a word such as *rich*, Greimas suggested that we determine its overall meaning by opposing it to its contradictory, *not rich*, its contrary,

poor, and its contradictory, *not poor*, in tandem. Moreover, as work with the semantic differential showed in the 1950s (mentioned above), there seem to be gradations within the binary oppositions themselves, which are due to culture-specific connotative processes. Anthropologist Lévi-Strauss (1958) further expanded opposition theory by showing that pairs of oppositions often cohere into sets forming recognizable units. In analyzing kinship systems, he found that the elementary unit of kinship was made up of a set of four oppositions: brother versus sister, husband versus wife, father versus son, and mother's brother versus sister's son. Lévi-Strauss suspected that similar sets, or orders, characterized oppositions in other cultural systems.

Although the idea goes right back to Aristotle and other ancient philosophers in various civilizations the cognitive importance of opposition was noticed by the psychologists Wilhelm Wundt (1832–1920) and Edward B. Titchener (1867–1927), who were the ones to term it opposition. Its use in semiotics and linguistics is due, as mentioned, to the Prague Circle linguists (Hjelmslev, 1939; Benveniste, 1946; Jakobson, 1939). The theory was criticized from the start as being useful but highly artificial and not really consistent with human psychology. However, already in the 1940s, Jakobson (1942) empirically showed that the theory of opposition predicts the sequence of phoneme acquisition in children, since he found that the sound oppositions that occur frequently are among the first ones learned by children, while those that are relatively rare are among the last ones to be acquired by children.

Another early criticism of opposition theory was the fact that it seemed to neglect the importance of a structural relation that is vital to understanding semiosis – associative structure. The study of such structure came, actually, to the forefront in the latter part of the 1970s, becoming a major trend within linguistics itself (Pollio et al., 1977; Lakoff and Johnson, 1980; Lakoff and Johnson, 1999; Fauconnier and Turner, 2002). American linguist George Lakoff and philosopher Mark Johnson set the ball rolling by claiming that a simple linguistic metaphor such as “My friend is a gorilla” is not an idiomatic exception to basic literal meaning, but a systematically formed utterance; it is a token of a cognitive associative structure that they called a *conceptual metaphor* (Lakoff and Johnson, 1980). This is why we can also say that John or Mary or whoever we want is a gorilla, snake, pig, puppy, and so on. Each specific linguistic metaphor (“John is a gorilla,” “Mary is a snake,” etc.) is an instantiation of a more general associative cognitive structure – *people are animals*. The question becomes: How are such concepts formed? They are formed through image schemata, as the two scholars argued (Lakoff, 1987; Johnson, 1987). The source for the people are animals conceptual metaphor seems to be an unconscious image that human personalities and animal behaviors are linked in some way. In other words, it is the consequence of an ontological imagistic opposition: *humans as animals*. This is a perfect example of how opposition manifests itself as an associative mechanism, not just a binary or multi-order one (as discussed above). In this case, the two poles in the opposition are not contrasted (as in night vs. day), but equated: humans as animals. This suggests that oppositional structure operates in a noncontrastive way at the level of figurative meaning.

Post-structuralism

The most severe critiques of opposition theory have revolved around the relative notion of *markedness* (Tiersma, 1982; Eckman et al., 1983; Andrews, 1990; Battistella, 1990). In oppositions such as night-versus-day, the question becomes: Which of the two poles is the more basic one (culturally or psychologically)? This is called the *unmarked* pole (the default one) and the other pole, the *marked* one (the one that stands out). It is easy to identify *day* as the unmarked form and *night* as its marked counterpart, since generally speaking we sleep at night and carry out conscious activities in the day. For example, we ask, “How many days are left before your birthday?” not “How many nights are left before your birthday?” Now, the problem is deciding which pole is marked and unmarked in a problematic opposition such as the male-versus-female one. The answer seems to vary according to the social context to which the opposition is applied. In patrilineal societies the unmarked form is male; but in matrilineal ones, such as the Iroquois one (Alpher, 1987), it appears to be female. Markedness, thus, seems to have social consequences. However, the late French semiotician-philosophers Michel Foucault (1926–1984) and Jacques Derrida (1930–2004) claimed that this whole approach to sign study was flawed, and was the unwitting source of social inequalities (Foucault, 1972; Derrida, 1976). Their refutations led to the movement known as post-structuralism, starting in the late 1950s and gaining prominence in the 1970s. In this movement, the oppositions identified by linguists and semioticians are seen as the result of an endemic logocentrism on the part of the analyst, not the result of some tendency present in the human brain. Saussure claimed that every sign was understandable in terms of its *différence* from other signs. In contrast to Saussure's idea of *différence*, Derrida coined the word *différance* (spelled with an “a,” but pronounced in the same way), to intentionally critique Saussurean theory. With this term, Derrida aimed to show that Saussure's so-called discoveries were unwitting, biased ones, because a science of language cannot succeed since it must unfold through language and thus partake of the slippage (as he called it) it discovers.

In effect, post-structuralists did not view markedness as a tool for investigating social-conceptual structure; they saw it, instead, as validating biases in that very structure. Derrida (1976, p. 237) went so far as to claim that our oppositions deconstruct themselves when analyzed reflectively, that is, they fall apart, revealing their biased origins:

In idealization, to an origin or to a “priority” seen as simple, intact, normal, pure, standard, self-identical, in order *then* to conceive of derivation, complication, deterioration, accident, etc. All metaphysicians have proceeded thus: good before evil, the positive before the negative, the simple before the complex, the essential before the accidental, the imitated before the imitation, etc. This is not just *one* metaphysical gesture among others; it is *the* metaphysical exigency.

But Derrida seems to have missed the fact that markedness is a theory, not a technique of mind manipulation. Markedness can actually be used to identify where the social stereotypes lie, not encode them. And this can, over time, actually lead to reversing markedness structure and the social inequalities it reflects. This has happened to the male-versus-female opposition in various modern societies. Such reversals exist across oppositions.

Post-structuralism made an impact on many fields of knowledge, not just semiotics and linguistics. As written language is the fundamental condition of knowledge-producing enterprises, such as science and philosophy, post-structuralists claim that these end up reflecting nothing more than the writing practices used to articulate them. However, in hindsight, there was (and is) nothing particularly radical in post-structuralism. Already in the 1920s, Jakobson and Trubetzkoy started probing the relativity of language oppositions in the light of their social and psychological functions. Basing their ideas in part on the work of German psychologist Karl Bühler (1879–1963), the Prague Circle linguists posited that language categories mirrored social ones. The goal of a true semiotic science, they claimed, was to investigate the isomorphism that manifested itself between signs and social systems. In other words, opposition theory was the very technique that identified social inequalities, not masked them.

Semiotics in qualitative research

Semiotics is well-suited as a tool for complementing or supplementing qualitative research in the cognitive sciences and education, providing a theoretical framework and *modus operandi* that aims to understand the connection among sign systems (language, symbolism, and so on) and specific forms of human behavior and understanding. The late semiotician Umberto Eco (1976, p. 74) provided five reasons for defining semiotics plausibly as a qualitative investigative tool:

1. It is an autonomous discipline that can bolster understanding in other disciplines, given that these are based on semiosis.
2. It has developed theories and practices that allow semioticians to determine how signs and sign systems are constructed and how they function psychologically, historically, and socially.
3. It generates hypotheses about human behavior and cognition.
4. It makes predictions about how societies and cultures will evolve.
5. Its findings can have an impact on the actual state of the world.

To these features, one can add the following relevant premises or principles that allow for the various applications of semiotics in diverse qualitative research paradigms (Danesi, 2007):

1. Signs and sign systems reveal similar properties of structure and function the world over.
2. Differences in the manifestations of these properties are due to the histories and traditions of particular cultures and societies.
3. Signs and sign systems entail culture-specific classifications of the world.
4. These influence the way people think, behave, and act.
5. Perceptions of “naturalness” are thus tied to sign systems; that is, what is often considered to be “common sense” turns out often to be “communal sense.”
6. Sign structures produce relativity effects.

The last principle implies that the signs we use constitute a guide for daily living. It does not claim, as some have maintained, that the meanings imprinted, say, in the symbols, vocabularies, and grammars of other cultures cannot be learned. Vocabularies bring out how language serves specific human needs in particular contexts and then doubles back on its users to guide their view of the world. Consider bodies of water as a simple, yet illustrative example. In English, we classify them as *lakes*, *oceans*, *rivers*, *streams*, *seas*, *creeks*, and so on. Clearly, bodies of water are important in English culture, perhaps because of the importance of navigation and other water-based activities in its history. People living in the desert have very few words for bodies of water, for obvious reasons. Because of the importance of water bodies in English (and other languages), the vocabulary is constructed to reflect this, including criteria such as size, which enters into the classificatory picture—*ocean-versus-lake*—as does width and length—*river-versus-stream*—among other oppositions. These sign structures shape how we come to perceive bodies of water and what they entail ontologically. Access to this ontological code is by acquiring the relevant vocabulary.

A sign selects what is considered important to be known and recalled from the infinite variety of things that are in the world—it imprints important information into a structured form which filters out unnecessary or subsidiary information, retaining within its signification core what is felt to be relevant. Although we create new signs to help us gain new knowledge and modify previous knowledge—that is what artists, scientists, writers, inventors, for instance, are always doing—by and large, we literally let our signs “do the understanding” for us, once we have acquired them in a rearing context. We are born into an already-fixed semiosphere that will largely determine how we view the world around us. Conducting research on human systems of meaning can clearly be informed practically by semiotic theory and method. We hardly realize the presence of unconscious semiotic mechanisms that manifest themselves in the signs we use (words and phrases used during conversations, in written texts, in kinesic and proxemic behaviors, and so on). The semiotic approach aims to understand how thought and feeling are intertwined with such verbal and nonverbal semiotic mechanisms.

One area where semiotics has been applied fruitfully is in education. A study by van der Schoot et al. (2009), for instance, examined the effects of the opposition consistent/inconsistent within a relevant arithmetic operation and markedness (the relational term being unmarked [“more than”] vs. marked [“less than”]) on word problem solving in a sample of 10–12 year old children

differing initially in problem-solving skill. The researchers found that less successful problem solvers will utilize a successful strategy only when the relational term is unmarked. In another significant and relative study, [Cho and Proctor \(2007\)](#) found that when classifying numbers as odd or even with left-right keypresses, performance was better with the mapping even-right than with the opposite mapping. Calling this a markedness association of response code (MARC) effect, the authors attributed it to compatibility between the linguistic markedness of stimulus and response codes. The MARC effect and its reversal are caused by a correspondence of the stimulus code designated as positive by the task rule with the positive-polarity right response code.

Semiotics is also expanding considerably in the context of changing technologies. For example, an area that is now utilizing the insights of semiotics more and more is in the study of social media discourse (see [Poulsen et al., 2018](#)). Hashtag literacy in particular is also becoming a relevant area of interest. A hashtag is a fascinating new kind of sign structure—it is a phrase beginning with the symbol “#” used as a way for tagging content so that interested users can locate it—that is, adding hashtags to a post allows users to find that post when searching for that topic. Hashtags can be used as well for finding users who are looking for topics on social media. Hashtags also have a “commentary” function. For example, a linguistic marker referencing the target of evaluation in a tweet not only renders the content searchable, but also constitutes a means to affiliate with values expressed in the tweet. This has led some linguists to call hashtags part of “searchable talk,” whose subtext is “Search for me and affiliate with my values” ([Zappavigna, 2019](#)). It also implies that hashtags can become ideological and politically subtle codes. In effect, digital systems now present new problems of semiotic analysis, expanding both semiotics itself and its potential applications.

Concluding remarks

The solution to the problem of what something *means* is not to examine meaning in any abstract way, but how it is encoded in specific ways through structures that have specific representational modalities—resemblance (iconicity), relation (indexicality), conventionality (symbolicity). As [Ogden and Richards \(1923\)](#) stressed in their classic study of this problem, meaning is to be understood not by analyzing isolated units, but by taking into account the forms that encode it. In this view, the real meaning unit is the sign.

Semiotics is ultimately a form of inquiry into how humans shape raw sensory information into knowledge-based categories through sign creation, that is, by using forms that stand for the categories. Signs are selections from the flux of information that is taken in by our senses allowing us to encode what we perceive as meaningful in it and, thus, to remember it. We are born into a system of sign use, called the semiosphere by the Estonian semiotician Juri Lotman (1922–1993), that will largely determine how we come to view the world around us ([Lotman, 1991](#)). The semiosphere, like the biosphere, regulates human behavior and shapes social evolution. However, although they can do little about the biosphere, humans have the ability to reshape the semiosphere any time they want. This ability to create new signs and sign systems is what distinguishes human semiosis from all other kinds of sign and signal systems in other species. Our textual resources, for instance, stimulate us to seek new meanings and new ways of seeing the world. These open up the mind, encourage creativity, and engender freedom of thought. As Charles [Peirce, 1931](#), vol. 2, p. 302) wrote so insightfully, it would seem that as a species we are inclined to “think only in signs”.

The adjective “qualitative” shapes sampling and data significantly and in many different ways. For example, the definition of “qualitative” bounds, enables, and disables specific kinds of research practices and discourses. Schwandt (1997) defined “qualitative” as a “not-so-descriptive adjective attached to the varieties of social inquiry that have their intellectual roots in hermeneutics, phenomenological sociology, and the Verstehen tradition” (p. 129). He explained that qualitative connects with quality as “an inherent or phenomenal property or essential characteristics of something (object or experience)” (p. 130). “Qualitative” can also be a (research) choice, a decision to take a different ontological turn away from realism, to take multiple epistemological directions, and to constitute one’s (research) world beyond quantification and numeric values. A particular type of data, material, or object of inquiry does not make data qualitative or quantitative, but the ways data and processes are used and those theoretical assumptions that guide data and sampling practices can infect either qualitative or quantitative. Thus, “qualitative” in this chapter is conceptualized as an intentional move beyond positivism, predictability, and quantification, a shift away from independent, singular elements, and generalization, toward a focus on experiences, emotions, affects, materiality and matter, an emphasis on the quality of entities and relations. We would like to note that the ways in which qualitative research is practiced operate in a continuum. For example, sampling and data do not operate as binaries (e.g., positivist and post-positivist research, traditional and experimental data) but scholars work with these concepts within a continuum where theoretical orientations and scholarly preferences can be viewed as degrees.

We are less interested in how sampling and data could be labeled, categorized, and practiced in one unified way. The purpose of this chapter is not to tell scholars how to sample or define data. Instead, we aim to diversify sampling and data practices in order to illustrate their multiple connections to theories, processes, world views, and subjectivities these concepts and practices carry. The ways data and sampling are approached and used form important choices scholars make and data and sampling are always connected and influencing each other. Similarly, decisions researchers make about data and sampling impact how data and sampling work together theoretically and practically. Ideally, these decisions should align and support similar onto-epistemological goals and purposes.

Data and sampling processes' intertextuality and relationality (how data and sampling relate to other qualitative concepts and practices) can create links to histories, discourses, other scholars, diverse materials, with endless traces of conceptual and practical differences. The call for logical and rational approaches to sampling and data is often challenged by the affective, sometimes surprising relationalities that is produced on/with scholars. However, this challenge acknowledge the different characteristics and assumptions while at the same time acknowledging that these characteristics blend and come together different ways. We aim to illustrate what these thoughts/doings/entanglements/relationships might produce in/out/through/beyond readily available and normative views of sampling strategies and data. We are working within an interesting paradox: data and sample are always already here even when we do not consciously attend to them. For example, any act of thinking, sensing, collecting, organizing, relating, and living are samples, selections, choices, and as such always signs of partiality.

In the past ten years, the notion of data has been troubled by an increasing number of scholars (see e.g., Koro-Ljungberg and MacLure, 2013; Koro-Ljungberg et al., 2017; Taylor et al., 2018). However, similar problematization has not occurred with the concept of sampling. Thus, in this chapter we introduce data and sampling (forms) that do not have it/they-ness, singular objectivity, and/or a clearly defined past. Instead, we advocate for processes and research designs which are relational and collective and as such always plural and multiple. Maybe all of us (scholars and qualitative researchers) are active data-making subjects and objects, actors and actants in collective sampling networks and ontological structures which enable data emergence and functioning. For example, how would one explain data which stubbornly lingers, emerging at some point as text, images, sensations, movements, edible pieces of ink and paper, disturbing sounds, noises, and later traces of these data entanglements return in relations established in dark and wet Finnish forests, reminders of sun rays in the sky space of a southwest art museum, and in the faces of happy children playing in the playground? In so many ways, scholarly practices and inquiry as we presently sense them are inseparably entangled with our past experiences, enactments, and appearances of data and more.

This chapter has been written up as a sample itself. A sample as used here and radically reconceptualized later in this chapter is no longer about systematic, methodological, or random selection of data but it reminds us about processes of selecting, filtering, being aware, acknowledging, choosing, relating, exercising agency, and living in posthuman worlds. Sampling creates knowledges and realities similar to the texts, ideas, and experiments shared within this chapter. Throughout this chapter we sample what and how to write about sampling and data practices. We sample and share samples in the form of examples, theoretical connections, and literature we utilize. We also selectively filter our thoughts and claims thus creating a sample of sampling. Our first cluster of samples focus on data, second set of samples addresses sampling, then we offer few exercises for readers to engage with data and sampling at deeper and more personal level. Finally, we conclude with sample where we address politics, drive, and extensions of data-sampling leaving readers with provocative questions.

Instead of rejecting sampling altogether, we want to recognize that sampling might be seen as a continuous process of choices, selections, and decisions that are entangled with the process of inquiry. During a research process we sample/decide/select: what to study, who to listen to, what to ask, which phenomena to interrogate, what to read, what to write, where to go, how to approach ethics and rigor, and more. At the same time, *we (researchers) are sampled by*, because something in the process chooses us: it can be an utterance, a written sentence, an image, an object, an atmospheric event, a splinter of material and ... and ... and In the end, we sample something and we are sampled by *something*.

Our samples draw from diverse traditions, experimentations, past, becomings in a shifting and pulsating fashion. Samples shared here are meant to be read and experienced in any order, with or without skipping over some parts, returning back to previous samples, through returns, and/or to be read over each other. They are connected by a rhythm which brings readers back and forth, far and distant from the data and sampling processes, and through the familiar and unfamiliar as different forms of unexpected provocations emerge. We find it important to problematize some historical and traditional discourses and practices therefore some of our samples offer radical reimagining and different ways to think with the futures (of data and sample).

Sample 1: Data history in qualitative inquiry

The history of data and their conceptualizations in qualitative research often stems from quantitative, positivist conceptualizations of data and science. Even today some qualitative scholars refer to data being sought, selected, collected, located within acceptable practices and visible formats (see e.g., Braun et al., 2017; Taylor and Francis, 2013). Much has been written about data collection in qualitative inquiry (see e.g., Guest et al., 2013; LeCompte and Preissle, 1993; Weller and Romney, 1988). More recently, data and data "collection" has moved beyond traditional qualitative approaches such as ethnographical interviews, observations, and collection of artifacts (see e.g., Wolcott, 1999) to include various visual, virtual, performative, collective, and hybrid forms of data (see e.g., Braun et al., 2017; Koro-Ljungberg et al., 2017). Yet many studies and qualitative research practices have been influenced by quantitative method and its claims to rigor, validity, reliability, and "scientific" evidence. While earlier qualitative data have been

considered to “capture and represent the real as experienced and lived”, they have also been influenced by human judgment and subjective interpretations. In the past many qualitatively scholars have been concerned how to measure, sample, validate, and systematically order data. Often data and their qualities have been reduced to the materials collected to evidence arguments. For example, [Denzin’s \(1970\)](#) edited collection noted how the “problem of data analysis” largely centers on researchers’ abilities to create “sound causal explanations” (p. 3). Later in the 1970s, qualitative data were connected with ethics and ethical responsibilities of a researcher. Scholars were concerned with the questions that addressed who owned data materials and who had rights to data. At that point it was noted that data can be dangerous and harmful, and their generation needs to be monitored. In the first edition of the handbook of qualitative research ([Denzin and Lincoln, 1994](#)) data were referenced as a type of empirical material and discussed in chapters dealing with other issues such as data collection and analytical processes. [Gubrium \(1988\)](#) discussed data as field data, whereas [Fielding and Fielding \(1986\)](#) distinguished between qualitative (real and deep data) and quantitative data (hard data). [Weller and Romney \(1988\)](#), in turn, proposed that data collection must be systematic with data collection methods independent from data those methods produced. Additionally, [Wolcott \(1994\)](#) discussed the need to use the term data since physical and natural science demanded it. Otherwise, ethnographers would just do fieldwork without dedicating anything to “be data” per se ([Wolcott, 1994](#)). Wolcott proposed data are the “first evidence of your efforts, something you gather or collect or generate or create, depending on the tradition in which you are working” (p. 3). Later, being influenced by poststructuralism [St. Pierre \(1997\)](#) proposed that she would continue to use the word data, but their meaning has now shifted. Not only did [St. Pierre \(1997\)](#) problematize the “data signifier” but she also proposed alternative forms of data such emotional data, dream data, sensual data, and responsive data.

One might also argue that data are always situated and shaped by researchers’ episto-ontological frames. For example, data within positivism is often collected, gathered, and systematically documented. Data are treated as an easily identifiable set of materials and the object of inquiry. In comparison, from a constructivist perspective data could be seen as created and potentially co-constructed. Data could be located in the mind, perceptions, imaginations, shared ideas, collective projects and more. Critical theorists might approach data as something to be emancipated, transformed, generated through critique and within different practices and networks of power. For many post scholars data are to be re-thought, re-conceptualized, deconstructed, performed, questioned in a variety of ways where the idea of stable data and data identifiers are problematized and troubled. Some new materialist scholars may approach data as forces, flows, matter, and forms of living relationally. Response-ability ([Haraway, 2016](#)) could be used to refer to the ethical uses and practices of new materialist data. Finally, from a decolonial perspective data are always in some ways connected to the land and ownership of land. Data, of these kinds, are linked to colonial practices, colonized knowledges, and various subjects and objects of colonialization.

Sample 2: Data reconceptualized

When one thinks about more contemporary forms and processes of qualitative data something interesting is always happening. However, to define or bound this “something” with data might be only partially possible, sometimes impossible, and even undesirable. Sometimes qualitative researchers may find that data take multiple forms, and they cannot put data (object) aside. Despite carefully and well-designed studies scholars might find themselves with too much, too little, too broad and too detailed, too personal and too communal data. Due to these reasons some scholars (see e.g., [Koro-Ljungberg et al., 2017](#)) have moved beyond data as interviews, observations, or artifacts toward relational data, more-than-human data, experimental data, performative and embodied lifedata, data that are so entangled with life that they become multiple. Data such as these are always plural, live, and stimulate or enact processes that work through life, move beyond and between life and yet still always return to lives. Data of these kind exemplify multiple simultaneous relations and connections, connectivity in past-presence, and diverse timespaces. They are theoretical formed and ontologically situated. Data as multiple and lived are stubborn and through this stubbornness, can offer scholars possibilities to inquiry differently, and immanently, and experimental ways.

Experimental data and speculative data aim to generate different futures and methodological worlds which may build on radical imagination (see [Haiven and Khasnabish, 2014](#)). Furthermore, speculative fiction and data’s futuristic orientation shape the inquiry, imagination, and processes of many qualitative researchers. For many followers of process philosophy, data are always already relational, but they also form and constitute immanent (dis)orienting interactive effects and various diverse forms of relational potentiality and actualizations. For example, increasing numbers of post-qualitative scholars continue to work through radical imagination, performative, more-than-human data and their disorienting effects to rethink and recreate more equitable futures. Ecological data, eco-data, relational data, data assemblages, intra-active data, multispecies symbiotic assemblages highlight some possibilities of more-than-human entanglements ([Koro-Ljungberg et al., 2017](#)) and the importance of global ecosystems and networks.

Those scholars who would like to counter data that are already predefined and pre-categorized by previous representationalist processes can adopt strategies which build on the relational, affective, sensual, and embodied elements of living and experiencing. For example, Vannini’s conceptualizations of data related to island life did not attempt to classify types of islands or forms of island life, but “how one kind of islandness is done ... [through] embodied experiences that islandness demands and affords” ([Vannini and Taggart, 2012](#), p. 227). For Vannini and Taggart, “islandness” is a creative, inventive, and becoming verb rather than a fixed and stable representation noun of “an island” as already imagined and constructed. Similarly, [Pink’s \(2014\)](#) digital–visual–sensory data considered “how the temporalities of visual ethnography research might be engaged to think about the future” (p. 414). Furthermore, the work of Manning, Massumi, and Sense Lab (<http://sensemab.ca/wp2/>) exemplifies experimental, living, and collective

methodologies (Manning, 2016, 2020). Thinking inquiry as a thought in the act (Manning and Massumi, 2014), turns inquiry into research-creations exemplifying data's various forms. From this perspective, data function as events in the making, "data and sampling" processes are considered as pragmatic and "useless" (without predetermined intentions) while highlighting the world of sensing, neurodiversity, textures, living, and touch. Research-creations create "thinking-doing" and "forms and forces of intellectuality that cut across normative accounts of what it means to know" (Manning, 2016, p. 27). In Springgay and Truman's (2016) Stone Walks project, walking with rocks generated unexpected connections with more-than-human worlds and data's materiality noted how rocks may move and reproduce prompting speculative thought on inhuman animacies. Furthermore, in Stephens and Delamont's (2006) two-handed ethnography, data of a dancing body met language, rhetoric, and cultural understandings, producing bodily and embodied ethnographic data. Finally, inefficient mapping was taken up in Knight's (2016) project studying playgrounds and urban planning. Playgrounds and urban spaces were seen as data "sites brimming with activity, the intensities brought on by collisions and interceptions between aspects and agents" (Knight, 2016, p. 22) rather than bounded, pre-determined and pre-conceptualized architecture and architectural functions.

While engaging in inquiry, sleeping, taking showers, and cooking dinner we wonder how data are actively persisting, returning, and continuously moving us and others. Is it possible that data circles back and returns in their different formation and through emerging and multiplying events? Performative notions and practices of data are often used by critical, postmodern/poststructural, process oriented, and posthuman among other scholars to emphasize data's vitality, relationality, and generativity. Data that was once bitten, eaten, and digested as a ball of transcribed interview text can possibly shape how other scholars wash data and encounter data while walking their dogs and thinking about their inquiries and participants. Relational data bring together event, actors, systems and always more. They connect life and events surprising scholars again and again. Data bags and bag-data bring scholars together, join lipsticks, laptops, and notepads carried in conference bags, Emily Muller meets Ikea bag, hotels, and personal belongings hidden and displayed in hotel rooms and more (Benozzo and Koro-Ljungberg, 2017). Data linger and morph through events, relations, lives, and processes researchers encounter. Data live in conference spaces, hotel rooms, black holes, books, rain drops and more. Data meet the boundaries of established spaces, ghostly and silently creeping and affecting and being affected by same and different data and datalives. Data produce so much and more. In some ways trying to capture these productions through fixed language and bounded scholarly techniques can be frustrating and also perceived as useless (Manning, 2020; Fairchild et al., 2022).

Data's relatedness and stubborn entanglements have less to do with fixed researcher identities, scholarly attachments, or stable emotional commitments. Instead, stubborn data entanglements exemplify continuously changing forms, processes, and relational contexts that persistently shift and change inquiry while being responsive to relational differences. Why does stubborn data become this or that has no reason at all? Proactive affirmation of data's generative potential produces. "We" are data together. Living and relational data become a "subject" and "subjects" not an "object" of inquiry. Stubborn data can also shape the politics of locations through diverse assemblages including events of remembering, counter memories, cartographies, and transformations (see Braiddotti, 2013). Bennett (2010) discusses assemblages as "ad hoc groupings of diverse elements, of vibrant materials of all sorts. Assemblages are living, throbbing confederations that are able to function despite the persistent presence of energies that confound them from within" (pp. 23–24). For Bennett assemblages are stubborn, persistent yet emergent. "The effects generated by an assemblage are, rather, emergent properties, emergent in that their ability to make something happen" (p. 24). An open-ended collective assemblage of data has vitality. These data assemblages are also vibratory; mood, style, content, membership change, alter and produce endless data variations in their relationality. Entangled states of A and B are understood as a single data entity. The fate of data is entangled with the fate of researcher, theories, philosophies, inquiries at large, practices, senses and more. "Knowledge is not a matter of reflecting at a distance; rather it is an active and specific practice of engagement. To know is to become entangled; objectivity requires that one take responsibility for one's entanglements" (Barad, 2007, p. 453).

Sample 3: Data as being with

In working on the idea of *constitutive withness or generative entanglement* Pyyhtinen (2016) draws from Deleuze and Guattari. According to Pyyhtinen (2016) the concept of with-ness "removes the focus from individual actors to dynamic relations" (p. 24). Understood in this way data begin, produce and are produced, emerge in the in-between, in the middle of things since "[n]othing exists solely in and by itself, but entities are what they are only in and through their relations with others" (Pyyhtinen, 2016, p. 18). Every entity like data is only constituted in relations, individualization is a collective and relational process where data come to be. Individuation in the fielding of singular-plural; always more than one. Data are traversed by lines, threats and forces. Stubborn data might operate also as a relational verb or relation par excellence. "There is no substance to entities other than difference and event, the occasion of their associations. They are grounded in multiplicity; each singular being is a multiplicity in itself" (Pyyhtinen, 2016, p. 25). Following Deleuze and Guattari (1987) data multiple is not about adding or summing up but subtracting data, multiple = $n-1$. Relational data form ontological positionings and as such data do not function as a knowledge project but constituting possibilities for data's becoming. Data to the n th power could also manifest themselves as *mad*, experimental, agentic data. Maybe also exception data and ignorant data. In its insisting and continuous questioning and stubbornness ignorant data may stimulate and produce innocence and creativity. Ignorant data refuse recognition and they are incapable to follow established norms.

Qualitative data do not function as a thing-in-itself but possibly a force and relational energy field producing complex ecological and relational patterns. These patterns shape the practices, mundane everydayness of scholars and participants at the same time

moving beyond this everydayness toward particular and specific event time. New imaginings, becomings, and reconceptualization's of data have produced and continue to create different assemblages, ecological, and material systems shaping inquiry, researchers' relationality and their thinking-doing. Many qualitative researchers might have become more hesitant and unsure about data while at the same time entangled more than ever before with unpredictable, surprising, and returning data. In some ways data have become an unanswerable maybe even a hypothetical question rather than an answer. Stubborn data cannot be taken for granted but they return with new tricks, creations, and companions. Qualitative scholars might no longer ask definitional, singular, and categorical questions about what data are *but* how and what stubborn and entangled data produce and how might it transform. What are some possibilities of data?

Field data	Sensual data
Observation data	Invisible data
Archival data	Sound data
Visual data	Memory data
Indigenous data	Rhythm data
Missing data	Invisible data
Natural data	Hard data
Inaccurate data	Sense data
Meta data	Big data
Performance data	Thick data
Coded data	Virtual data
Raw data	Response data
Interview data	Ghost data
Land-data	Entangled data
Dream data	
Real data	Escaped data

Sample 4: Sampling processes and strategies in conventional humanistic qualitative research

The approaches of sampling in qualitative research have evolved significantly from the aims and processes that quantitative sampling signify. Many elements contribute to the differences found in sampling processes. For example, the definition of sampling varies, sampling units differ (from participants to textual elements, to sounds, place and space, matter and materiality, affect, and bodily sensations), scholars' approaches to saturation and timing of the sampling itself. [Guest et al. \(2013\)](#) referred to sample as a collection of a subset of units (people or otherwise) from a larger population related to a particular study. Oftentimes, scholarly conventions present among researchers highlights the importance of transparency and the need to provide an indication of quality and validity of research for scholars outside specific research traditions. [Marshall \(1996\)](#) suggests the aim of all quantitative sampling approaches is to "draw a representative sample from the population, so that the results of studying the sample can then be generalized back to the population" (p. 522) where participants are often selected randomly based on predetermined hypotheses and sample sizes. The trans-disciplinary nature of qualitative research sees sampling approaches that give richness, deeper insights and in-depth understandings of a particular phenomenon (see e.g., [Staller, 2021](#)). Instead of relying on the randomly selected representative samples of a particular group or population, qualitative sampling is often based on the purposive and flexible invitation of participants and the selection of diverse data (descriptions, narratives, documents, artifacts, visual, virtual, collective, and hybrid forms of data etc.) which might evolve even throughout the research process. Qualitative sampling requires specific attention to the research process and its evolution, ethical considerations, and study contexts, including the holistic socio-political and material elements of the study: the individuals, the temporal, spatial and situational elements. The following section describes the logic of sampling from a conventional (humanistic) qualitative research perspective. Sampling in conventional qualitative research is often concerned with representativeness and meeting of predetermined criteria. Sampling as an *a priori* process is also exemplified in dissertation proposals and Institutional Review Board processes. It has been argued that *a priori* sampling could form a useful yet tentative plan for more flexible and situated research approaches (see [Gentles et al., 2015](#)). Instead of proposing a stable understanding of qualitative sampling, we then problematize and reconceptualize sampling and its strategies. We aim to diversify the understanding of sampling and illustrate its multiple forms and the choices scholars make ongoingly during any qualitative research project.

This kind of sampling is often connected to post positivist, interpretivist, and sometimes critical traditions, in which the focus is on lived experiences and affects, on how people make sense of their (local) lives in diverse contexts, oftentimes in and through language. In many cases sampling is directly informed by and dependent on the methods selected such as qualitative interviews, participatory research approaches, and ethnographic methods. For example, interview methods and sampling within the context of interviews vary based on the disciplinary backgrounds of the researchers and the epistemological and ontological presuppositions of scholars ([Guba and Lincoln, 1994](#)). Sampling of this kind implies the need to indicate the *number and characteristics of the participants* interviewed and the reasons that led to choosing these participants. Sampling also involves decisions about timing

and when participants will be invited to join the study and research activities. In addition, scholars make decisions about the degree of their involvement in sampling processes. [Guest et al. \(2013\)](#) suggest that scholars should clarify how much control researchers have over sampling and recruitment and consider how flexible their study designs might be.

Sampling within conventional qualitative research is also concerned with numbers. Yet within the existing literature on qualitative interviews and on the selection/sampling of participants, a precise number of participants is rarely indicated. The study's purpose and the ontological, epistemological, methodological, and practical issues can guide the sampling process. [Brinkmann and Kvale \(2015\)](#) suggested 5–25 participants for a qualitative study depending on the aim of the research project. Some authors argue that if the research purpose is to provide a rich and dense account of an event or experience then even one interview may be appropriate ([Becker, 2012](#)). The number of participants may also depend on the balance between representativeness (in a broad sense) and the quality of the responses when obtaining sufficient information. If the purpose of a study is to establish commonalities or allow for comparison, then a larger sample of participants are likely to be appropriate. If one was to be concerned with data saturation, the number of participants should not be so small that it makes data saturation difficult and at the same time sample should not be too large to compromise in-depth and detailed data analysis.

Some researchers argue that ideally data collection through sampling should continue until saturation ([Morse, 1994](#)) or until informal redundancy ([Lincoln and Guba, 1985](#)). For some scholars the concept of saturation, originally derived from grounded theory ([Glaser and Strauss, 1967](#)), is considered the “gold standard” and saturation is reached when new participants or new data do not produce any additional theoretical or thematic insights (theoretical or thematic saturation). However, some scholars consider the adoption of saturation of sampling as a generic indicator of quality inappropriate and inaccurate across different theoretical orientations where rich, detailed, and in-depth data can be interpreted in multiple different ways.

Convenience sampling refers to the sample where participants are conveniently available for the researcher and are willing to take part in the research project (e.g., [Staller, 2021](#)). [Alvesson and Ashcraft \(2012\)](#) cautioned against overemphasizing the assumed richness of responses and relying too heavily on interviewees/participants that researchers have easy access to. While convenience sampling might be suitable sampling strategy for studies where research questions do not bound, characterize, or call for a unique set of participants, the outcomes may also decontextualize the phenomena being research by overly divorcing participants from the research aims. Even if the qualitative sampling of interviewees/participants or data did not need to represent a particular group or population to serve generalization, the convenience sample might limit insights gained from the data.

In addition to convenience sampling, purposive sampling strategies can serve the aims of a specific qualitative research project (see e.g., [Staller, 2021](#); [Marshall, 1996](#)). These include, studying a broad range of participants (maximum variation sample), outliers (deviant sample), participants who have specific experiences (critical case sample) or participants with special expertise or experience (key informant sample). Participants might also suggest others for the research project, which some scholars call a snowball sample. [Guest et al. \(2013\)](#) also propose homogenous sampling which highlights similarities among participants; intensity sampling that intensify the phenomenon under study; politically important sampling that includes politically sensitive cases; and criterion sampling builds on pre-existing criterion. The work of Joseph Maxwell cited in [Emmel \(2014\)](#) highlighted how realistic sampling balances ideas and evidence, theory and practice. Realistic sampling choices demonstrate different how the relationship between ideas and evidence are conceptualized. In addition, inductive, emergent or theoretical sampling (in grounded theory terms) allow for groups not specified in the original research design when data collection and analysis process evolves and more samples are needed ([Guest et al., 2013](#)). These different sampling procedures are expected to serve the research questions and produce interviewees, participants, individuals, groups, settings where and for whom the phenomenon being studied is most likely to occur.

Sample 5: Alternatives to representational sampling strategies

The idea of sampling as a form of representative reality can be troubled from postmodern, post-structural, post-qualitative and other post perspectives. The representational forms of sampling logic are based on a process that creates structures and categories, stasis out of movement and proliferation (see [MacLure, 2013a](#)). Even though structures and categories could be helpful to order and investigate the known and unknown, this kind of sampling easily reinforces simplified categories or hierarchies of representation, which are often based on identity, similarity, and opposition ([Löytönen, 2017](#)).

Representational uses of sampling may also be seen as a process of separation to demarcate the field, for example identifying individuals, newspaper and video, sites and places that might be relevant and give “information” about the phenomena under investigation. Sampling could imply a selection and process to define a perimeter/and edge/and end of the field and then it becomes a limitation. If sampling is a decision to separate, what are we leaving outside and aside? If sampling is taking a decision, it implies that we are dividing (to take a decision derives from the Latin *de caedere* = to cut out), but can this action be also violent, difficult to carry out, and full of contradictions? And what about what is left aside? Where is this potentially relevant excess gone?

Scholars who are interested in situated and fragmented knowledges, who are excited about experimental and artistic forms of inquiry, and those who desire to emphasize relationality and more-than-human approaches may find many alternatives. For example, one can think of sampling as a form of cutting together-apart, an agential cut ([Barad, 2007](#)). Cutting is never a separation, or it is never a complete separation (a final break which separate subject from object), because things are always already in relation.

Each sample cuts out a part of the world, excluding and including some things over other things, which is cutting together-apart or cutting apart-together. The researcher can choose which part to use from a recorded or transcribed sentence and which part can be cut. A research paper presents a specific selection of the world and could be different if other cuts/sentences were used. We can read the research paper through the technology of a computer which determines what we see. In this way agential cuts are inclusions and exclusions, we are responsible and accountable for the cuts we make, we practice our response-ability as an ethical sensibility and response to others (Haraway, 2016).

Barad's concepts of agential cut and cutting together-apart offers useful perspectives of inclusion and exclusion practices within qualitative research. According to Barad (2007), a cut is never a definitive separation, it is never a complete division (a kind of break that separates the subject from the object), because the data, the subjects, texts, images, videos are always and already in relationship with us, between them and more. Other scholars have created concepts that also open new potentialities in conceptualizing research-creation processes through non-hierarchical or non-categorical approaches. Some of these approaches could also be used in the context of sampling, for example concepts of assemblage (Deleuze and Guattari, 1987); entanglement (Barad, 2007); or actor network (Latour, 2007). As indicated with Barad's concepts of agential cut and cutting together-apart, these concepts might reframe how sampling is theorized and practiced, how things are always already relational and how they come together, or are brought together in different formations. Thus, different theoretical frameworks and concepts might offer scholars approaches beyond readily available and normative views of sampling strategies in qualitative research. The different ways of framing and theorizing sampling might then offer scholars possibilities to sample differently, or sample in a more nuanced and fluid way, and thus maybe move toward more relevant research creations in each specific project. We might call these kinds of sampling approaches the "logic of unholy mixture" as described by Lecerle (2002, p. 54; see also MacLure, 2013b).

What if qualitative sampling was understood as an assemblage, an entanglement, a collage, choices ranging from theoretical, philosophical, data, textual, visual, toward assemblages, and entanglements? Might this open up research practices for novel entanglements that allow thinking and practicing differently? These kinds of differentiating perspectives on sampling may allow thinking-feeling, movement-moving and more.

Purposive sampling	Open sampling
Convenience sampling	Awkward sampling
Representative sampling	Singularity sampling
Typical sampling	Deviant sampling
Intensity sampling	Loose sampling
Maximum variation sampling	Minimum variation sampling
Homogeneous sampling	Heterogeneous sampling
Revelatory case sampling	Opaque case sampling
Critical case sampling	Indiscriminate case sampling
Opportunistic sampling	Normative sampling
Confirming sampling	Disconfirming sampling
Snowball sampling	Waterfall sampling
Theoretical sampling	Poetic sampling

Sample 6: Exercise in perhaps-cutting

Experimental approaches to sampling need to be practiced, tried, and exercised. Let's begin!

"... [the] pastime of gathering very different objects and materials together and trying to classify them started in the sixteenth century, and this marked the beginning of the phenomenon of Wunderkammern or cabinets of curiosities which brought together various pieces from the world around us, a world deemed wonderful and full of amazing surprises. In the Wunderkammer, very different objects and materials – naturalia et artificialia – were juxtaposed, being placed alongside each other in daring combinations. Wunderkammern were places filled with natural (naturalia) and artificial (artificialia et mirabilia) things: optical instruments and games, mechanical toys, natural history specimens, maps, precious gems, anatomical limbs or anomalies, lenses, mirrors, strange objects, etc. They were places where things were accumulated and piled up without any clear order and where connections came into being without there having to be a logical reason for them.

Benozzo and Gherardi (2020, p. 151).

"... the wondrous is a meta-historical category that has been defined all along the eighteenth century, didactically first and foremost, as a form of knowledge, that is, a very special half-way stage, a kind of mental suspension that lies between ignorance and knowledge, which marks the end of ignorance and the beginning of knowledge.

Lugli (2006, p. 126).

Create your own Wunderkammern

Take half a day off
 choose a place that you love:
 a city, a village or ...
 wander around and gather or buy *naturalia, articialia et mirabilia*

After one week
 Take half a day off
 choose a place that you love:
 a wood or a garden or a river or ...
 wonder around and gather what you like (*naturalia, articialia et mirabilia*)

After another week
 Take half a day off
 choose a place that you love
 prepare your own Wunderkammer
 invite some friends
 introduce your Wunderkammern
 allow your friends to play with your *naturalia, artificialia et mirabilia*

Sample 7: Exercise in *ritornello*

Create your own ritornello

Gather your research journals or notebooks.
 Explore the journals/notebooks by looking for repetitions,
 repetitive phrases, repetitive expressions, wordings, visuals.
 Assemble these repetitions,
 bring them together
 in new combinations,
 maybe in a collage.
 Create your own *ritornello*, a *refrain*,
 or "little song"
 which might start to establish
 "the beginnings of order in chaos [Deleuze and Guattari \(1987, p. 323\)](#)).

Note: The ritornello, refrain, as noted by [MacLure \(2016\)](#) accomplishes holding and bringing togetherness to various heterogeneous elements.

Sample 8: (Political) drive of data and sampling

adjective

adjective: data-driven

1. determined by or dependent on the collection or analysis of data.

One could argue that (qualitative) data and sampling strategies in qualitative inquiry are always political and moving. As noted earlier qualitative research has often been seen as the less significant and important form of inquiry, with concerns raised over validity and reliability. Similarly, data and sampling strategies used by qualitative research are sometimes questioned as non-scientific, subject to bias with a lack of rigor ([Ercikan and Roth, 2006](#)). This has been coupled with a skeptical view of research that is focused on the "posts" (postmodernism, poststructuralism, postcolonialism, posthumanism, feminist materialism) where policy makers in particular do not always see the value of fluid and nuanced worldviews ([Wolgemuth et al., 2021](#)). In much of education research there has been a focus on randomized controlled trials and research that invokes a "what works" view of education ([Styles and Torgerson, 2018](#)). Generally, this has been a response to social policy desires to narrow educational attainment gaps to reduce inequality (see [Biesta, 2010](#)). However, it could be argued that this focus on data and sampling has driven aspects of education

policy to become more performative, more about metrics, linked to return on investment narratives (Heckman, 2000). Data monitors attendance (Bodén, 2015), governance (Williamson, 2016), attainment and assessment (O’Keefe, 2017; Kippin and Cairney, 2021), progress (Fairchild, 2020), employability (Molesworth et al., 2011) and drives policy decisions (Williamson, 2018). For many data become a currency that places a certain type of value on outcomes and, in turn, drives outcomes-based research and pedagogy (Gunn, 2018; Bradbury and Roberts-Holmes, 2018). Data and systematic and random sampling strategies, therefore, become political, part of the capitalist machine—an output, a mode of being, a performative tool—producing dividual subjectivities (Deleuze, 1992) and segmenting bodies (Deleuze and Guattari, 1987).

What might be possible if we let data drive ... where would that take us? (Figs. 1 and 2)

Fig. 1 Data driven gender-in-the-making.

Fig. 2 Data storytelling multiple positionality.

Data and sampling processes are not neutral; they hold the politics and mattering of research and research practice. The way they are **driven** can have significant ramifications for the outcomes of research and practice. If we start to problematize the notion of data and sampling and where they **drive** us we can re-think and reconsider what **data driven** research might look like. [Deleuze and Guattari \(1987\)](#) developed the term line of flight as a neologism that highlights the infinite possibilities available when we break from accepted and known norms of doing and being. Lines of flight can act as disrupting mechanisms, they can jolt or shock us, they can excite us and reveal different ways to think about phenomena.

Methods-as-affinity-groups were the means to generate data for this inquiry, however, I was left wondering what 'data' would be presented to me during the field work. I was left considering a number of points, such as 'What is data? What does data feel about these books descriptions? Does data want to be represented, coded and classified?

[Fairchild \(2017, p. 81\).](#)

When we start to rethink **data driven** research we can consider how data becomes a driver powered by forces of Deleuzo-Guattarian desire ([Deleuze and Guattari, 1987](#)) ... data become a desiring machines. Desire is conceptualized as a positive and active actualization of reality rather than as a psychological state of lack. Desire is a force or an intensity, an affect which can manipulate meaning and relations, inform and fabricate meaning and generate intensity. Desire is more than an individual need for something, it shapes and connects people, objects, things, matter, discourse and politics. It can reveal how data-bodies are made and remade and the physical, material and political affects that shape them. Forces of desire become machinic, they become self-replicating and a multiplicity—desire can only be understood by what it produces collectively and not by the individual components of the machine. Therefore, a desiring machine is a data-body (in the broadest sense—see [Baugh, 2010](#)) that connects with other bodies when assemblages coalesce and form around particular events producing a new body, experience or happening ([Deleuze and Guattari, 1983](#)). The concepts of lines of flight and desiring machines can reframe to nature and notion of **data driven** as a productive force or intensity that generates a multitude of new possible insights rather than the data being used to denote the fixity of "truth" or "certainty".

Data-as-a-desiring-machine ([Fairchild, 2017](#)) highlights the instability of the actuality of "data" and "sampling" that can be used to predict or fashion a response to a research question. Scholars have argued whether the traditional notions of data and sampling are even required in a post-positivist world ([Denzin, 2013](#)). If we start to question the form and function of research and what it might require, perhaps rather than **data driven** research we might stumble over data ([Brinkman, 2014](#)) and sampling, they might be a splinter or be a nuisance ([Benozzo et al., 2013](#)) or something we wonder at [MacLure \(2013a\)](#). Following these lines of flight can reveal the productive nature of data and sampling assemblages that do their own **driving** (see [Fairchild et al., 2022](#)). Reconsidering what **data driven** research might look like can highlight the influence of affects and sensations that are immanent, exciting, entangling, provocative, disturbing and politically informed. This can be exemplified in the work of those using "post" ontologies and epistemologies as a means to provide new and different understandings of research and intersectionality (see [Koro-Ljungberg et al., 2017](#); [Rantala, 2019](#); [Taylor et al., 2020](#)). Data-desiring-machines become situated, relational and located, affected and connected, where the interest is on what knowledge(s) **data driven** might produce rather than the "truths" it might tell.

Data driven desiring machines that can "engineer partial objects, flows and bodies, and that function of units of production" ([Deleuze and Guattari, 1983, p. 39](#)). Data become a force and flow, a line of flight, machinic in its connections with bodies, in constant motion, becoming, affecting, data-ing. Maybe the question we should be asking about **data driven** is:

What could happen if qualitative researchers were to shift their focus from acting on, manipulating, or analysing data to data's working on the researchers themselves or taking the initiative?

[Koro-Ljungberg \(2016, p. 54\).](#)

Fairchild et al.'s book assembles and produces events that problematize conference spaces highlighting the relationality and materiality between data and bodies. They encourage moving beyond linear progress narratives that become caught up in research practices, instead they call for researchers to:

undo the assumption – common when thinking of what has happened in 'the past' – that the workshop happenings (and the 'data' they produced and created) are lying in limbo waiting 'there' for some human to come back to it/them to resuscitate and make meaning out of it/them. We trouble these linear meaning-making logics.

[Fairchild et al. \(2022, p. 10\).](#)

When we follow lines of flight and become caught up in data-as-a-desiring-machine it becomes possible to re-envisage **data driving**, encouraging research to move beyond "what works" to "what is produced". Perhaps it is time for a quantum leap to move beyond representational logic where "the 'undoings' of methods-as-usual in post-qualitative inquiry promises ... to open a new empirical landscape for ... research investigations" ([Taylor, 2017, p. 322](#)). Maybe the examples in this chapter reveal of some of the possibilities for thinking and researching otherwise when we let **data drive**.

Sample 9: (Im)possible questions shaping data and sampling futures

Can we think about data and sampling without considering global pandemics and ecological crises?
 Can we live without data and sampling and what might that living look like?
 What might replace data?
 How might shifting data assemblage function in ways promoting response-ability?
 What potential implications will a shift from an object thinking (data and sample as objects) toward process (data and sample as processes) and subject (agency of data and sample)?
 How can relational data and sampling help us to move beyond the notion of a/the/one truth in qualitative inquiry?
 How can we live with and by multiplicities in data and sampling, and life?
 How might data and sampling help us in making propositions and understanding potentialities?

Qualitative interviewing has today become a key method in the human and social sciences, and also in many other corners of the scientific landscape such as education and the health sciences. Some have even argued that interviewing has become *the* central resource through which the social sciences—and society—engage with their issues of concern (Rapley, 2001). For as long as we know, human beings have used conversation as a central tool to obtain knowledge about others. People talk with others in order to learn about how they experience the world, how they think, act, feel and develop as individuals and in groups, and in recent decades such knowledge producing conversations have been refined and discussed as *interviews*.

In a classic text, Maccoby and Maccoby defined the interview as “a face-to-face verbal exchange, in which one person, the interviewer, attempts to elicit information or expressions of opinion or belief from another person or persons” (Maccoby and Maccoby, 1954, p. 449). This definition can be used as a very general starting point, but different schools of qualitative interviewing have interpreted, modified, and added to such a generic characterization in many different ways, as we shall see.¹

Qualitative interviews in a conversational world

Human beings are conversational creatures that live a dialogical life (Mulhall, 2007). Humankind is, in the words of philosopher Stephen Mulhall, “a kind of enacted conversation” (p. 58). From the earliest days of our lives, we are able to enter into proto-conversations with caregivers in ways that involve subtle forms of turn-taking and emotional communication. The dyads in which our earliest conversations occur are known to be prior to the child’s own sense of self. Of course, most of us do learn to talk privately to ourselves, and hide our emotional lives from others, but this is possible only because there was first an intersubjective communicative process with others. Our relationships with others—and also with ourselves—are thus conversational. In order to understand ourselves, we must use a language that was first acquired conversationally, and we try out our interpretations in dialog with others and the world. The human self exists only within what philosopher Charles Taylor has called “webs of interlocution” (Taylor, 1989, p. 36). Our very inquiring and interpreting selves are conversational at their core; they are constituted by the numerous relationships we have, and have had, with other people (Brinkmann, 2012).

Unsurprisingly, conversations are therefore a rich and indispensable source of knowledge about personal and social aspects of our lives. Since the late nineteenth century (in journalism) and the early twentieth century (in the social sciences), the conversational process of knowing has been conceptualized under the name of *interviewing*. The very term interview itself testifies to the dialogical and interactional nature of human life. An interview is literally an *inter-view*, an inter-change of views between two persons, conversing about a theme of mutual interest (Brinkmann and Kvale, 2015). *Con-versation* in its Latin root means “dwelling with someone” or “wandering together with,” and the root sense of *dia-logue* is that of talk (*logos*) that goes back and forth (*dia-*) between persons (Mannheim and Tedlock, 1995, p. 4).

Thus conceived, the concept of conversation in the human and social sciences should be thought of as much broader than simply another specific and technical research method. Certainly, conversations in the form of interviewing have been refined into a set of techniques, but they are also a mode of knowing and a fundamental ontology of persons. As philosopher Rom Harré has put it: “The primary human reality is persons in conversation” (Harré, 1983, p. 58). Cultures are constantly produced, reproduced, and revised in dialogs among their members (Mannheim and Tedlock, 1995, p. 2).

The pervasiveness of the conversation in human life is both a burden and a blessing for researchers who wish to employ qualitative interviews. On the one hand, qualitative interviewing appears as a very significant tool with which to understand central features of our conversational world. Contrary to widespread critiques of qualitative research that it is too subjective, one might

¹This article is a condensed and revised version of earlier work, notably Brinkmann (2013).

argue—given the picture of the conversational reality painted here—that qualitative interviewing is in fact the most *objective* method of inquiry when one is interested in qualitative features of human experience, talk, and interaction (at least if objectivity means being adequate to a subject matter), since qualitative interviews seems uniquely capable of grasping these features of our lives.

On the other hand, it is also a burden for qualitative interviewers that they use conversations to study a world, which is always already itself saturated with conversation. If Mulhall is right that humankind is a kind of enacted conversation, then the process of studying humans by the use of interviewing is analogous to fish wanting to study water. Fish surely “know” what water is in a practical, embodied sense, but it can be a great challenge to see and understand the obvious, that with which we are so familiar (Brinkmann, 2012). Similarly, some interview researchers might think that interviewing others for research purposes is easy and simple to do, because it employs a set of techniques that everyone masters in virtue of being capable of asking questions and recording the answers. This, however, is clearly an illusory simplicity, and many qualitative interviewers, even experienced ones, will recognize the frustrating experience of having conducted a large number of interviews (which is often the most fun part of a research project), but having ended up with a huge amount of data, in the form of perhaps thousands of pages of transcripts, and not knowing how to transform all this material into a solid, relevant, and thought-provoking analysis. Too much time is often spent on interviewing, while too little time is devoted to preparing for the interviews, and subsequently analyzing the empirical materials. And, to continue on this note, too little time is normally used to reflect on the role of interviewing as a knowledge-producing social practice in itself. Interviewing, in short, is often simply taken for granted.

The history of qualitative interviews

In one obvious sense, the use of conversations for knowledge producing purposes is likely as old as human language and communication. The fact that we can pose questions to others about things that we are unknowledgeable of is a core capability of the human species. It expands our intellectual powers enormously, since it enables us to share and distribute knowledge between us. Without this fundamental capability, it would be hard to imagine what human life would be like. It is furthermore a capacity that has developed into many different forms and ramifications in human societies. Already in 1924 could Emory Bogardus, an early American sociologist and founder of one of the first US sociology departments (at the University of Southern California) declare that interviewing “is as old as the human race” (Bogardus, 1924, p. 456), and he discussed similarities and differences between the ways that physicians, lawyers, priests, journalists, detectives, social workers, and psychiatrists conduct interviews with a remarkable sensitivity to the details of such different conversational practices.

In a more specific sense, and more essentially related to qualitative interviewing as a scientific human enterprise, conversations were used by Thucydides in ancient Greece as he interviewed participants from the Peloponnesian Wars to write the history of the wars. At roughly the same time, Socrates famously questioned—or we might even say *interviewed*—his fellow citizens in ancient Athens, and used the dialogs to develop knowledge about perennial human questions related to justice, truth, beauty, and the virtues. In recent years, some interview scholars have sought to rehabilitate a Socratic practice of interviewing, not least as an alternative to the often long monologues of phenomenological and narrative approaches to interviewing (see Dinkins, 2005, who unites Socrates with a hermeneutic approach to dialogical knowledge), and also in an attempt to think of interviews as practices that can create a knowledgeable citizenry and not merely chart common opinions and attitudes (Brinkmann, 2007). Such varieties of interviewing have come to be known as dialogic and confrontational (Roulston, 2010, p. 26), although care should be taken not to understand the latter term as implying some disrespectful practice of catching the interviewee in contradictions or something like that.

If we jump to more recent times, interviewing notably entered the human sciences with the advent of Sigmund Freud’s psychoanalysis around 1900. Freud is famous for his psychoanalytic theory of the unconscious, but it is significant that he developed this revolutionary theory (which, in many ways, changed the Western conceptions of humanity) through therapeutic conversations, or what he referred to as the talking-cure. Freud conducted several hundreds of interviews with patients that used the patients’ free associations as a conversational engine. The therapist/interviewer should display what Freud called an “even-hovering attention” and catch on to anything that emerged as important (Freud, 1963). Freud made clear that research and treatment go hand in hand in psychoanalysis, and Steinar Kvale has more recently pointed to the rich potentials of psychoanalytic conversations for qualitative interviewing even today (Kvale, 2003).

Many human and social scientists from the first half of the twentieth century were well versed in psychoanalytic theory, including those who pioneered in qualitative interviewing. Jean Piaget, the famous developmental researcher, had even received training as a psychoanalyst himself, but his approach to interviewing is also worth mentioning in its own right. Piaget’s (1930) theory of child development was based on his interviews with children (often his own) in natural settings, frequently in combination with different experimental tasks. He would typically let the children talk freely about the weight and size of objects, or, in relation to his research on moral development, about different moral problems (Piaget, 1932), and he would notice the manner in which their thoughts unfolded.

Raymond Lee, one of the few historians of interviewing, has charted how Piaget’s so-called “clinical” method of interviewing became an inspiration for Elton Mayo, who was responsible for one of the largest interview studies in history at the Hawthorne plant in Chicago in the 1920s (Lee, 2011). This study arose from a need to interpret the curious results of a number of practical experiments on the effects of changes in illumination on production at the plant: It seemed that work output improved when the lighting of the production rooms was increased, but also when it was decreased. This instigated an interview study with

more than 21,000 workers being interviewed for more than an hour each, leading to the whole human relations approach to work life (Roethlisberger and Dickson, 1939).

Not just Piaget, but also the humanistic psychologist Carl Rogers, was an important pioneer of interviewing. Like Freud, Rogers developed a conversational technique that was useful both in therapeutic contexts (so-called client-centered therapy), but also in research interviews, which he referred to as the “non-directive method as a technique for social research” (Rogers, 1945). As he explained, the goal of this kind of therapy/research was to sample the respondent’s attitudes toward herself: “Through the non-directive interview we have an unbiased method by which we may plumb these private thoughts and perceptions of the individual” (p. 282). In contrast to psychoanalytic practice, the respondent in client-centered therapy/research is a client rather than a patient, and the client is the expert. Although often framed in different terms, many contemporary interview researchers still conceptualize the research interview in line with Rogers’ humanistic, non-directive approach, valorizing the respondents’ private experiences, narratives, opinions, beliefs, and attitudes.

As the Rogerian nondirective approach to interviewing gained in popularity, early critiques of this technique also emerged. In the 1950s, the famous sociologist David Riesman and his colleague Mark Benney criticized it for its lack of interviewer involvement and they warned against the tendency to use the level of “rapport” (much emphasized by interviewers inspired by therapy) in an interview to judge its qualities concerning knowledge. They thought it was a prejudice “to assume the more rapport-filled and intimate the relation, the more ‘truth’ the respondent will vouchsafe” (Riesman and Benney, 1956, p. 10). In their eyes, rapport-filled interviews often spill over with “the flow of legend and cliché” (p. 11), since interviewees are likely to adapt their responses to what they take the interviewer expects from them (see also Lee, 2008, for an account of Riesman’s discussion of interviewing and its relevance even today).

The mid-20th century witnessed a number of other large interview studies that remain classics in the field, but which have also shaped public opinion about different issues such as *The Authoritarian Personality* by the well-known critical theorist Adorno and co-workers (Adorno et al., 1950), Kinsey’s *Sexual Behavior in the Human Male* (Kinsey et al., 1948), and Dichter’s *The Strategy of Desire* (1960) that communicates the results of an interview study about consumer motivation for buying a car. The latter was an important precursor to the market and consumer research that continues to be among the largest areas of qualitative interviewing in contemporary society.

Roulston (2010) has made a comprehensive list of some of the most recent varieties of interviewing and also of more traditional ones (here shortened a bit):

- *Neo-positivist* conceptions of the interview are still widespread and emphasize how the conversation can be used to reveal “the true self” of the interviewee (or the essence of her experiences), resulting in solid, trustworthy data that are only accessible through interviews with the interviewer having a non-interfering role.
- *Romantic* conceptions stress that the goal of interviewing is to obtain revelations and confessions of the interviewees by intimacy and rapport. These conceptions are somewhat close to neo-positivist ones, but put much more weight on the interviewer as an active and authentic midwife facilitating the “birth” of the inner psyche of the interviewee.
- *Constructionist* conceptions reject the romantic idea of authenticity and favor an idea of a subject that is locally produced in the situation. There is thus a focus on the situational practice of interviewing, and a distrust toward discourses of data as permanent “nuggets” to be “mined” by the interviewer. Instead, the interviewer is often portrayed as a “traveler”, involved in the co-construction of whatever happens in the conversation together with the interviewee (Brinkmann and Kvale, 2015).
- *Postmodern* and *transformative* conceptions stage interviews as dialogic and performative events that aim to bring new kinds of people and new worlds into being. The interview is depicted as a chance for people to get together and create new possibilities for action. Some transformative conceptions focus on potential decolonizing aspects of interviewing, seeking to subvert the colonizing tendencies that some see in standard interviewing, while other forms focus more on the researchers’ experience, sometimes expressed through autoethnography, an approach that seeks to unite ethnographical and autobiographical intentions (Ellis et al., 2011).

Different forms of qualitative research interviews

The semi-structured, face-to-face interview represents merely one form an interview may take, and there is today a huge variety of other forms. Each form has certain advantages and disadvantages that researchers and recipients of research alike should be aware of. I shall here describe how qualitative interviews may differ in terms of *structure*, the *number of participants* in each interview, and also different *media*. After this I will go on to look at two broad ways of theorizing interview talk.

Structure

It is quite common to make a distinction between structured, semi-structured, and unstructured interviews. This distinction, however, should be thought of as a continuum ranging from relatively structured to relatively unstructured formats. I use the word “relatively,” because, on the one end of the continuum, as Parker (2005) argues, there really is no such thing as a completely structured interview “because people always say things that spill beyond the structure, before the interview starts and when the recorder has been turned off” (p. 53). Utterances that “spill beyond the structure” are often quite important, and are even sometimes

the key to understanding the interviewee's answers to the pre-structured questions. One line of criticism against standardized survey interviewing actually concerns the fact that meanings and interpretive frames that go beyond the predetermined structure are left out with the risk that the researcher cannot understand what actually goes on in the interaction.

We might add to Parker's argument that there is also no such thing as a completely *unstructured* interview, since the interviewer always has an idea about what should take place in the conversation. Even some of the least structured interviews such as life history interviews that only have one question prepared in advance (e.g., "I would like you to tell me the story of your life. Please begin as far back as you can remember and include as many details as possible") provide structure to the conversation by framing it in accordance with certain specific conversational norms rather than others. Another way to put the matter is to say that there are no such things as non-leading questions. All questions lead the interviewee in certain directions, but it is generally preferable to lead participants only to talk about certain *themes*, rather than to specific *opinions* about these themes.

So, it is not possible to avoid structure, nor would it be desirable, but it is possible to provide a structure that is flexible enough for interviewees to be able to raise questions and concerns in their own words and from their own perspectives. This does not imply a total elimination of structure, but demands a careful preparation and reflection of how to involve interviewees actively, how to avoid flooding the conversation with social science categories, and how to provoke interviewees respectfully to bring contrasting perspectives to light (Parker, 2005, p. 63). In spite of this caveat—that neither completely structured nor completely unstructured interviews are possible—it may still be worthwhile to distinguish between more or less structure with semi-structured interviews somewhere in the middle as the standard approach to qualitative interviewing.

- *Structured interviews*: These are employed in surveys and are typically based on the same research logic as questionnaires: Standardized ways of asking questions are thought to lead to answers that can be compared across participants and possibly quantified. Interviewers are supposed to "read questions exactly as worded to every respondent and are trained never to provide information beyond what is scripted in the questionnaire" (Conrad and Schober, 2008, p. 173). Although structured interviews are useful for some purposes, they do not take advantage of the dialogical potentials for knowledge production that are inherent in human conversations. They are passive recordings of people's opinions and attitudes, and often reveal more about the cultural conventions of how one should answer specific questions than about the conversational production of social life itself. Since this article is concerned with qualitative interviewing, which characteristically has as a much more flexible format with the interviewer being able to follow up freely on interviewee answers, I shall leave the standardized and structured interview format behind and refer the interested reader to Conrad and Schober, who do in fact discuss creative ways of developing this traditional social science technique further (Conrad and Schober, 2008).
- *Unstructured interviews*: At the other end of the continuum lie interviews that have little preset structure. These are for example the life story interview seeking to highlight "the most important influences, experiences, circumstances, issues, themes, and lessons of a lifetime" (Atkinson, 2002, p. 125). What these are for an individual can only be known in the course of spending time with the interviewee, which means that the interviewer cannot prepare for a life story interview by devising a lot of specific questions, but must instead think about how to facilitate the telling of the life story. After the opening request for a narrative, the main role of the interviewer is to remain a listener, withholding desires to interrupt, and sporadically asking questions that may clarify the story. The life story interview is a variant of the more general genre of narrative interviewing about which Wengraf's (2001) *Qualitative Research Interviewing* gives a particularly thorough account, focusing on biographical-narrative depth-interviews. These need not concern the life story as a whole, but may address other, more specific, storied aspects of human lives, building on the insight of narratology that human beings experience and act in the world through narratives. With the more focused narrative interviews we get nearer to semi-structured interviews as the middle ground between structured and unstructured interviews.
- *Semi-structured interviews*: Interviews in the semi-structured format are sometimes equated with qualitative interviewing as such (Warren, 2002). They are probably also the most widespread ones in the human and social sciences and are sometimes the only format given attention in textbooks on qualitative research. Compared to structured interviews, semi-structured interviews can make better use of the knowledge producing potentials of dialogs by allowing much more leeway for following up on whatever angles are deemed important by the interviewee, and the interviewer has a greater chance of becoming visible as a knowledge producing participant in the process itself, rather than hiding behind a preset interview guide. And, compared to unstructured interviews, the interviewer has a greater saying in focusing the conversation on issues that he or she deems important in relation to the research project.

One definition of the semi-structured qualitative research interview reads: "It is defined as an interview with the purpose of obtaining descriptions of the life world of the interviewee in order to interpret the meaning of the described phenomena" (Brinkmann and Kvale, 2015, p. 6). The key words here are (1) purpose, (2) descriptions, (3) life world, and (4) interpretation of meaning, which I shall now unfold in turn:

- (1) *Purpose*: Unlike everyday conversations with friends or family members, qualitative interviews are not conducted for their own sake; they are not a goal in themselves, but are staged and conducted in order to serve the researcher's goal of producing knowledge (and there may be other, ulterior goals like obtaining a degree, furthering one's career, or positioning oneself in the field etc.). All sorts of motives may play a role in the staging of interviews, and good interview reports often contain a *reflexive* account and discussion of both individual and social aspects of such motives (does it matter, for example, if the interviewer is a woman, perhaps identifying as a feminist, interviewing other women?). Clearly, the fact that interviews are conversations

conducted for a purpose, which sets the agenda, raises a number of issues having to do with power and control that are important to reflect upon for epistemic reasons as well as for ethical ones.

- (2) *Descriptions*: In most interview studies, the goal is to obtain the interviewee's descriptions rather than reflections or theorizations. In line with a widespread phenomenological perspective, interviewers are normally seeking descriptions of *how* interviewees experience the world, its episodes and events, rather than speculations about *why* they have certain experiences. Good interview questions thus invite interviewees to give descriptions such as "Could you please describe a situation for me in which you became angry?", "What happened?", "How did you experience anger?", "How did it feel?" (of course, only one of these questions should be posed at a time), and good interviewers tend to avoid more abstract and reflective questions such as "What does anger mean to you?", "If I say 'anger', what do you think of then?", "Why do you think that you tend to feel angry?". Such questions *may* be productive in the conversation, but interviewers will normally defer them until more descriptive aspects have been covered.
- (3) *Life world*: The concept of the life world goes back to the founder of phenomenology, Edmund Husserl, who introduced it in 1936 in his book *The Crisis of the European Sciences* to refer to the intersubjectively shared and meaningful world in which humans conduct their lives and experience significant phenomena (Husserl, 1954). It is a pre-reflective and pre-theorized world in which anger, for example, is a meaningful human expression in response to having one's rights violated (or something similar) before it is a process occurring in the neurophysiological and endocrinological systems (and "before" should here be taken in a logical, rather than temporal, sense). If anger did not appear to human beings as a meaningful *experienced phenomenon* in their life world, there would be no reason to investigate it scientifically, for there would in a sense be nothing to investigate. In qualitative research in general, as in qualitative interviewing in particular, there is a primacy of the life world as experienced, since this is prior to the scientific theories we may formulate about it. This was well expressed by Maurice Merleau-Ponty, another famous phenomenologist, who built on the work of Husserl:

All my knowledge of the world, even my scientific knowledge, is gained from my own particular point of view, or from some experience of the world without which the symbols of science would be meaningless. The whole universe of science is built upon the world as directly experienced [i.e., the life world; my addition], and if we want to subject science itself to rigorous scrutiny and arrive at a precise assessment of its meaning and scope, we must begin by re-awakening the basic experiences of the world of which science is the second order expression.

Merleau-Ponty (1945, p. ix).

Objectifying sciences give us second-order understandings of the world, but qualitative research is meant to provide a first-order understanding through concrete description, e.g., as obtained by interviewing.

- (4) *Interpret the meaning*: Even if interviewers are generally interested in how people experience and act in the world prior to abstract theorizations, they must nonetheless often engage in interpretations of people's experiences and actions as described in interviews. One reason for this is that life world phenomena are rarely transparent and "monovocal," but are rather "polyvocal" and sometimes even contradictory, permitting multiple readings and interpretations. Who is to say what someone's description of anger signifies? Obviously, the person having experienced the anger should be listened to, but if there is one lesson to learn from twentieth century human science (ranging from psychoanalysis to poststructuralism) it is that we, as human subjects, do not have full authority concerning how to understand our lives, because we do not have—and can never have—full insight into the forces that have created us (Butler, 2005). We are, as Judith Butler has argued, authored by what precedes and exceeds us (p. 82), even when we are considered—as in qualitative interviews—to be authors of our own utterances. The interpretation of the meanings of the phenomena described by the interviewee can favorably be built into the conversation itself, since this will at least give the interviewee a chance to object to a certain interpretation, but it is a process that goes on throughout an interview project.

I have now introduced a working definition of the semi-structured qualitative research interview and emphasized four vital aspects: Such interviews are structured by the interviewer's *purpose* of obtaining knowledge; they revolve around *descriptions* provided by the interviewee; such descriptions are commonly about *life world phenomena* as experienced; and understanding the meaning of the descriptions involves some kind of *interpretation*. Although these aspects capture what is essential to a large number of qualitative interview studies now and in the past (and likely many of the future as well), all aspects can be challenged, and there are no principles of qualitative interviewing that are always proper and correct.

Individual and group interviews

It is not just the interviewer's agenda and research interests that structure the interaction in an interview. Unsurprisingly, the number of interviewees also plays an important role. As the history of interviewing testifies, the standard format of qualitative interviewing is with one person interviewing another person, but many other varieties exist that deserve to be mentioned.

- *Group interviews*: There is today an increasing use of group interviews. These have been in use since the 1920s, but became standard practice only after the 1950s, when market researchers in particular developed what they termed focus group interviews

to study consumer preferences. Today, focus groups dominate consumer research and are also often used in health, education, and evaluation research, but are in fact becoming increasingly common across many disciplines in the social sciences.

In focus groups, the interviewer is conceived as a “moderator,” who focuses the group discussion on specific themes of interest, and she or he will often use the group dynamic instrumentally to include a number of different perspectives on the given themes (Morgan, 2002). Often, group interviews are more dynamic and flexible in comparison with individual interviews, and they may be closer to everyday discussions. They can be used, for example, when the researcher is not so much interested in people’s descriptions of their experiences as in how participants discuss, argue, and justify their opinions and attitudes.

The standard size for a focus group is between six to ten participants, led by a moderator. Recently, qualitative researchers have also experimented with groups of only two participants (sometimes referred to as “the two-person interview,” although there are literally three people if one counts the interviewer), mainly because it makes the research process easier to handle than with larger groups, where people will often not show up. The moderator introduces the topics for discussion and facilitates the interchange. The point is not to reach consensus about the issues discussed, but to have different viewpoints articulated about an issue. Focus group interviews are well suited for exploratory studies in little known domains, or about newly emerging social phenomena, since the dynamic social interaction that results may provide more spontaneous expressions than in individual interviews.

- *Individual interviews:* Individual interviews with one interviewer and one interviewee may sometimes be less lively than group interviews, but they have a couple of other advantages: First, it is often easier for the interviewer in one-on-one interviews to lead the conversation in a direction that is useful in relation to the interviewer’s research interests. Second, when studying aspects of people’s lives that are personal, sensitive, or even taboo, it is preferable to use individual interviews that allow for more confidentiality and often make it easier for the interviewer to create an atmosphere of trust and discretion. And there are obviously also certain themes that simply just demand the presence of one person telling a story without being interrupted or gainsaid by other participants, such as in biographical research.

Interviewing using different media

It is noteworthy that the otherwise standardized format of “face-to-face interaction” was only named early in the twentieth century by the sociologist Charles Horton Cooley (see Briggs, 2007, p. 553), but was since constructed as “primordial, authentic, quintessentially human, and necessary” (p. 553). It is sometimes forgotten that also the face-to-face interview is a kind of situated interaction that is mediated by this particular social arrangement that has a history. Other well-known media employed in qualitative interviewing include the telephone and the internet, and we shall now take a brief look at differences between face-to-face, telephone, and internet interviews.

- *Face-to-face interviews:* In face-to-face interviews people are present not only as conversing minds, but as flesh and blood creatures that may laugh, cry, smile, tremble, and otherwise give away so much information in terms of gestures, body language, and facial expressions. Interviewers thus have the richest source of knowledge available here, but the challenge concerns how to use it productively. In most cases, how people look and act is forgotten once the transcript is made, and the researcher carries out her analyses using the stack of transcripts rather than the embodied interaction that took place. This is a problem especially when a research assistant, or someone else who was not the interviewer, transcribes the interview, because in that case, it is not possible to note and recall all the non-verbal signs and gestures that occurred. If possible, it is therefore preferable for the interviewer herself to transcribe the conversations, and it is optimal to do so relatively soon after the conversations are over (e.g., within a couple of days), since this guarantees better recollection of the body language, the atmosphere, and other such non-transcribable features of the interaction.
- *Telephone interviews:* According to Shuy (2002), the telephone interview has “swept the polling and survey industry in recent years and is now the dominant approach (p. 539)—often in a very structured format. In a research context, the use of telephone conversations was pioneered by conversation analysts, who were able to identify a number of common conversational mechanisms (related to turn-taking, adjacency pairs such as questions-answers etc.) from the rather constricted format that is possible over the telephone. The constricted format itself may have been productive in throwing light on certain core features of human talk.

Shuy emphasizes a number of advantages of telephone interviewing such as reduced interviewer effects (important in structured polling interviews, for example), better interviewer uniformity, greater standardization of questions, greater cost-efficiency, increased researcher safety (Shuy, 2002, p. 540), and—we might add—better opportunities for interviewing people who live far away from the interviewer. In qualitative interviewing, it is not possible (nor desirable) to avoid “interviewer effects,” because the interviewer herself is the research instrument, so only the latter couple of points are relevant in this context. However, Shuy also highlights some advantages of in-person interviewing as against telephone interviewing such as more accurate responses due to contextual naturalness, greater likelihood of self-generated answers, more symmetrical distribution of interactive power, greater effectiveness with complex issues, more thoughtful responses, and the fact that they are better in relation to sensitive questions (pp. 541–544). The large majority of interviews that are characterized as “qualitative” are conducted face-to-face, mainly because of these advantages listed by Shuy.

- *Internet interviews*: Email and chat interviews are varieties of internet interviewing with email interviewing normally implying an asynchronous interaction in time, with the interviewer writing a question and then waiting for a response, and chat interviews being synchronous or “real time” (Mann and Stewart, 2002). The latter can approach a conversational format that resembles face-to-face interviews with quick turn takings. When doing online ethnographies, e.g., in virtual realities on the internet, chat interviews are important (see Markham, 2005, on online ethnography). One advantage of email and chat interviews is that they are “self-transcribing” in the sense that the written text itself is the medium through which researcher and respondents express themselves, and the text is thus basically ready for analysis the minute it has been typed.

Disadvantages of such interview forms are related to the demanded skills of written communication. Not everyone is sufficiently skilled at writing to be able to express themselves in rich and detailed ways. Most research participants are more comfortable when talking, rather than writing, about their lives and experiences. However, as the psychiatrist Finn Skårderud has pointed out, there are some exceptions here, and Skårderud emphasizes in particular that internet conversations can be useful when communicating with people who have problematic relationships to their bodies (e.g., eating disorders). For such people, the physical presence of a problematic body can represent an unwanted disturbance (Skårderud, 2003).

In concluding on the different media of interviewing it should be emphasized that all interviews are mediated, even if only by the spoken words and the historical arrangement of questioning through face-to-face interaction, and there is no universally correct medium that will always guarantee success. Interviewers should choose their medium according to their knowledge interests, and should minimally reflect on the effects of communicating through one medium rather than another. That said, most of the themes that qualitative interviewers are interested in lend themselves more easily to face-to-face interviewing because of the trust, confidentiality, and contextual richness that this format enables.

Analytic approaches to interviewing

Before closing, I shall give a brief introduction to different analytic approaches to interviewing ordered by a simplified dichotomy, which should really be thought of as a continuum. I will introduce a distinction between interview talk as primarily descriptive phenomenological *reports* (concentrating on the “what” of communication) and interview talk as primarily discursive *accounts* (chiefly concerned with the “how” of talk). Phenomenological approaches to interviewing try to get as close as possible to precise descriptions of *what* people have experienced, while other analytical approaches (found, for example, in certain schools of discourse analysis and conversation analysis) focus on *how* people express themselves and give accounts occasioned by the situation in which they find themselves. The two approaches are contrasted in Table 1 below.

- *Interviews as research instruments*: Researchers working from the former perspective (corresponding to the left hand side of the Table) believe that interview data can reflect the interviewees’ reality outside the interview. They consequently seek to minimize the interviewer’s effects on coloring interviewees’ reports of their reality. The interview becomes a research instrument in the hands of interviewers, who are supposed to act receptively in order to interfere as little as possible with the interviewee reporting. The validity of the interviewees’ reports becomes a prime issue, when one approaches interviewing primarily as a research instrument. And since interviews normally concern things experienced in the past, this significantly involves considerations about human memory, and about how to enhance the trustworthiness of human recollections.

In one of the few publications to discuss the role of memory in interviewing, Thomsen and Brinkmann (2009) recommend that interviewers take the following points into account if they want to help interviewees’ improve the reporting of specific memories:

- Allow time for recall and assure the interviewee that this is normal
- Provide concrete cues, e.g., “the last time you were talking to a physician/nurse” rather than “a communication experience”
- Use typical content categories of specific memories to derive cues (i.e., ongoing activity, location, persons, other people’s affect and own affect)
- Ask for recent specific memories
- Use relevant extended time line and landmark events as contextual cues, i.e., “when you were working at x” to aid the recall of older memories

Table 1 Inspiration for slicing the cake of qualitative interviewing in this manner comes from Talmy (2010) and Rapley (2001), who builds on a distinction from Seale between interview-data-as-resource and interview-data-as-topic.

<i>Conception of interviewing</i>	<i>Research instrument</i>	<i>Social practice</i>
Conception of interview data	Reports, interview data as resource	Accounts, interview data as topics
Standard analytic focus	Lived experience—the “what”	Situated interaction—the “how”
Typical interviewer style	Receptive	Assertive
Main challenge	Validity of interviewee reports	Relevance of interviewee accounts
Paradigmatic background	Phenomenology, grounded theory etc.	Discourse analysis, conversation analysis etc.

- Ask the interviewee for a free and detailed narrative of the specific memory (adapted from [Thomsen and Brinkmann, 2009](#)).

Following such guidelines is meant to result in interviewee descriptions that are valid (which means that they are about what the researcher intends them to be about), and close to the “lived experience” of something, or what was called experiences of life world phenomena earlier in the article. Although phenomenology is one typical paradigm to frame interviews analytically as research instruments, many other paradigms do so as well, for example Grounded Theory, which has been developed since [Glaser and Strauss \(1967\)](#) with the intent of developing theoretical understandings of phenomena grounded in empirical materials with meticulous coding of data being a significant technique.

- *Interviewing as a social practice*: In contrast to those approaches that see interviewing as a research instrument designed to capture the “what” of what is reported as accurately as possible, others working from more constructionist and situated perspectives have much greater analytic focus on the “how” of interviewing. They view interviewing as a social practice; as a site for a specific kind of situated interaction, which means that interview data primarily reflect “a reality constructed by the interviewee and interviewer” ([Rapley, 2001](#), p. 304). The idea of obtaining valid reports that accurately reflect a reality outside the conversational situation is thus questioned, and the main challenge becomes instead how to explain the relevance of interview talk. That is, if what is said in an interview is a product of this social practice itself, how can it ever be relevant to conduct interviewing? Postmodern interviews, emphasizing performative and transformative aspects of interviewing, represent attempts to meet this challenge by arguing that if interviews do not concern a reality outside themselves, they can instead be used to perform or facilitate social change.

People subscribing to the right hand side of [Table 1](#) believe that interview talk should be conceived as accounts. Unlike reports, which refer to experiences in the interviewee’s past that can be articulated when prompted, accounts are answers that are “normatively oriented to and designed for the questions that occasion them” ([Talmy, 2010](#), p. 136). If interviewee talk is best understood as accounts, it must be seen as a kind of social action that has effects and *does* something in the situation of which it is a part. This perspective on interviewing is shared by some discourse analysts and conversation analysts, who limit themselves to analyzing interview talk as situated interaction.

Readers may wonder at this point if two approaches that are so different can co-exist. My own pragmatic answer is that they can, at least if the two approaches are not brought to an extreme: It is true that there are huge problems associated with viewing the interview as a site for pure reports of the past (we know too much about the constructive role of human memory, and of how the social practice of interviewing mediates what is said, to take this seriously). But it is certainly also true that there are problems associated with denying that we can refer more or less accurately to past experiences (and those who follow the right-hand side of [Table 1](#), and deny that data can be resources for understanding experiences of the past, still believe that their own communicative practice, materialized in their texts, are about matters outside this specific text).

So, taken to extremes, both approaches become absurd, and I believe that it is now time for the two (sometimes opposed) camps to learn from one another and realize that they need not exclude one another. In my view, some of the most interesting interview studies are those where analyses of the “what” and the “how” fertilize each other in productive ways.

Conclusions

In this article, I have given a broad introduction to qualitative interviewing. I have tried to demonstrate that the human world is a conversational reality in which interviewing takes a privileged position as a research method, at least in relation to a number of significant research questions that human and social scientists want to ask. Throughout the article, I have kept an eye to interviewing as a social practice, and we should be careful not to naturalize this kind of human interaction unreflectively, i.e., by viewing it as a particularly natural and unproblematic way of staging human relationships.

Furthermore, I introduced a number of distinctions that are relevant when mapping the field of qualitative interviewing, e.g., between different levels of structure, different numbers of participants, and different media of interviewing. I also provided a detailed presentation of semi-structured life world interviewing, as the standard form of qualitative interviewing today.

I finally gave particular attention to two broad analytic approaches to interviewing: On the one side, experience focused interviewing seeking to elicit accurate reports of what interviewees have experienced (in broad terms the phenomenological positions), and, on the other side, language and interaction focused interviewing (discourse oriented positions) that focus on the nature of interview interaction in its own right.

In my eyes, none of these approaches are superior *per se*, but they enable researchers to pose different kinds of questions to their materials. Too often, however, interviewers forget to make clear what kinds of questions they are interested in, and also forget to consider whether their practice of interviewing and their analytic focus enable them to answer their research questions satisfactorily.

Introduction: our perspectives and biases

We are not cutting people open. We are educators. Our work is about learning and teaching through social interaction and other communicative channels. We value pedagogies of reflective praxis that celebrate complexity and nuance. We value the transformative powers of both human and material agencies, and thus we value the use of focus groups to renew or transform education purposes, policies, and practices. Consequently, we are not going to write another traditional history of focus group research or another focus group research "cookbook." There are already many of those (e.g., [Lee, 2010](#); [Morgan and Hoffman, 2004](#)). Instead, we are going to do several things a bit differently in this chapter. First, we are going to lead with visuals and use text to support and unpack them. With rapidly changing communication practices afforded by digital technologies—graphic novels and informational texts, YouTubes, multimodal texts as normative, and data visualization dominating news stories in most media forms—this seems to make common 2.0 cultural sense. Second, whereas most handbook and encyclopedia chapters tend to be retrospective, we are taking a prospective stance in this chapter, concentrating more on where focus group research is going than where it has been. Finally, although we provide some history and practical advice on the use of focus groups in research, our arguments are largely conceptual and speculative ([Fig. 1](#)).

In the first part of this chapter, we review our previous conceptual work, which we believe is part of a radical methodological "break" or "turn" in focus group research. In the second part of the chapter, we argue that experimental uses of focus groups have induced an ontological/epistemological/axiological cascading effect that has all but forced us to reimagine social science research as productive in [Foucault's \(1977, 1988\)](#) sense of this term—as always producing new forms of life ([Wittgenstein,](#)

Fig. 1 Figured Worlds in focus groups timeline.

1953) or new ways of being in the world (Heidegger, 1962). Finally, we comment on the promise and potentials of focus group research after this methodological “break” or “turn.”

Looking at spectrums of various kinds, we see that qualitative researchers have pushed for focus group research to lead the way in blurring the lines between science and art, epistemology and ontology, fact and value; they have also pushed for research to have greater political teeth—not just to document the world but to change it strategically, usually in the interest of greater inclusion, equity, and social justice (Fig. 2).

Retrospect: traditional uses of focus groups in social science research

We like to think in/with the metaphor of spectrums because they help us see the wide range of variants or inflections of all social phenomena, as well as the many ways we might study them. On the traditional/historical end of the focus group spectrum, scholars have commonly imagined focus groups in relatively static terms. For example, they have proposed that the ideal size of focus groups is five to eight participants (e.g., Morgan and Hoffman, 2004). In this regard, they have argued that three or fewer participants often results in awkward pauses, long silences, and inertia in getting conversations off the ground. Conversely, groups larger than eight participants tend to leave some people voiceless and often results in tangent hopping. From this historical perspective and especially in market research and psychological research, it is common to stage only one focus group of about one to 3 h in duration. Finally, in most extant focus group research, the researcher/facilitator has typically chosen the topics for discussion and directed/controlled the flow of talk during discussions.

At the other end of this spectrum, dynamism, contingency, unpredictability, and transformation have been celebrated and practiced. From this perspective, scholars have foregrounded “the fundamental entanglement of the material and the nonmaterial, the human and the nonhuman” as “key to thinking and acting differently in the world” (Dimitriadis, 2016, p. 144). This move is fundamentally important given the decentering of the self in contemporary identity theory and the powerful insights from the sociology of scientific knowledge (especially Latour, 2007) about the distributed locus of agency in the ongoing production of material and social phenomena.

Fig. 2 Focus groups as transformative forces of/for social change.

Additionally, scholars frequently deploy Barad's (2007) construct of "intra-action" to work in this new ontological/epistemological/axiological space. Intra-action "signifies the mutual constitution of entangled agencies ... those distinct agencies do not precede, but rather emerge through, their intra-action" (Barad, 2007, p. 33). "Intra-action" thus replaces "interaction," rejecting the idea that individual entities exist separate from each other and only later enter into relations/relationships. Instead, intra-action views agency as a co-constitutive dynamism of forces (Barad, 2007, p. 141) in which humans, non-human entities, and discourses are never separate things but are constantly co-creating both each other and reality itself. From an intra-action perspective, objectivity becomes impossible because people and scientific instruments are always already part of the process that produces facts or outcomes (Fig. 3).

In our work, we started to notice that strategic assembly often intra-acted with the content, mood, tone, and outcomes of focus group conversations. Further, we found researchers such as Collins (2007), who studied sex workers in the Philippines, met their participants where they were already, where they felt safe (cafés, for example), in groups they had already formed, and within in activities they had already made their own. Collins did not schedule meetings, but instead was constantly on the lookout for when members got together on their own at different times on different days in different places, and she folded herself into their activities. Documenting their conversations and interactions, Collins was able to gather information that was more authentic—issuing from natural interactions relatively undetermined by the researcher. Although this approach is not always feasible or desirable, it speaks to the importance of strategic assembly in focus group research.

What about parties in conflict? In bringing heterosexual couples experiencing conflict together (or any social group—small or large—experiencing conflict), for example, what considerations would researchers make? Might they stage homogeneous focus groups for wives and husbands followed by heterogeneous ones? In these heterogeneous focus groups, would couples be the participants, or would the groups not include couples but just be cross-gendered groups? If couples were selected and arguments between couples emerged, how would facilitators handle this either within or beyond the scheduled focus groups?

More generally, what is the facilitator's role anyway? As focus group research has evolved, facilitators have increasingly been inclined to take a back seat and allow the groups to manage the topics and the flow of conversation. What about considering assigning the facilitative role to a research participant or to rotate that role across participants? Even when researchers take a back seat, though, how can they help participants go deeper without being intrusive or overly directive?

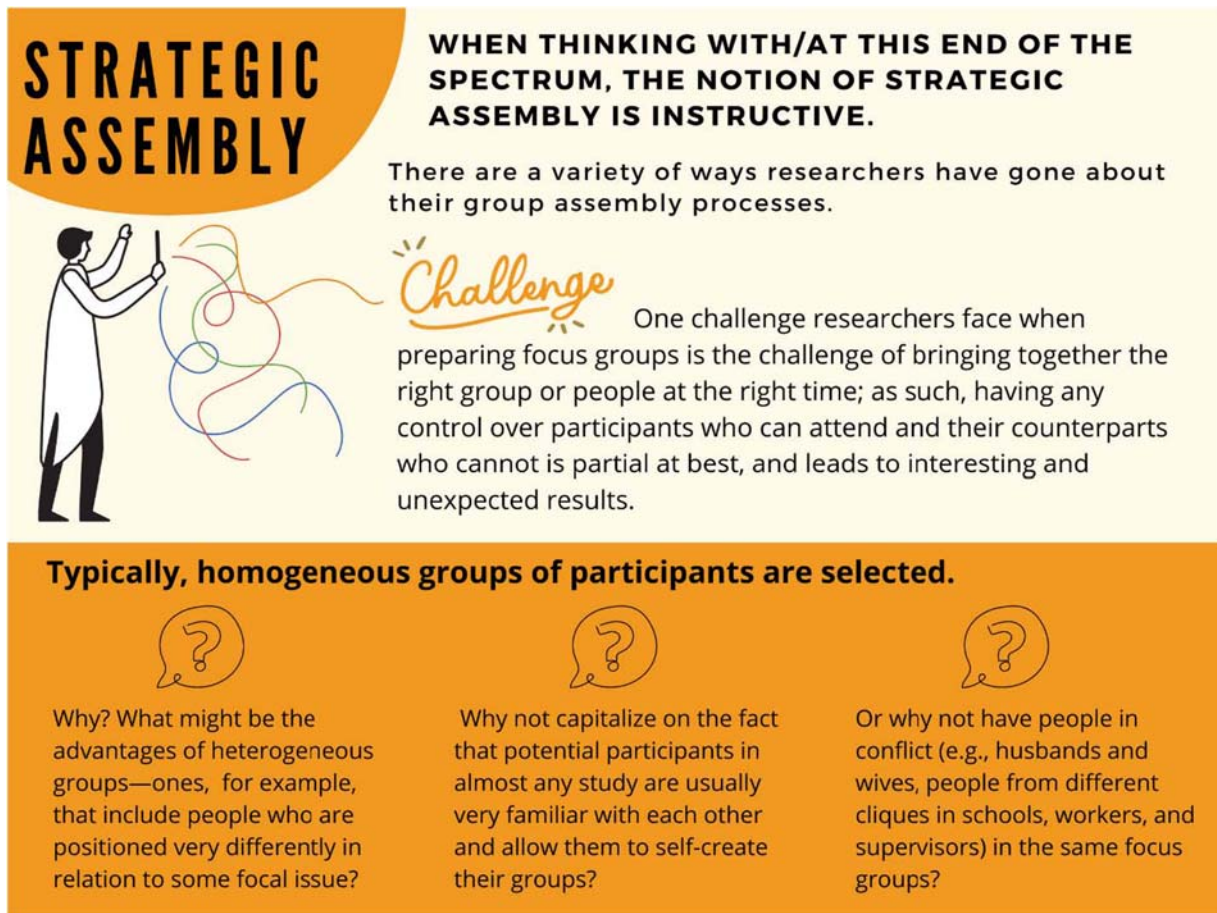

Fig. 3 Strategic assembly.

Multiple functions of focus group research

Kamberelis and Dimitriadis (2005) noted that focus groups have served three primary functions in qualitative research over the years: a pedagogical function, a political function, and an inquiry function. The *pedagogical* function of focus group work foregrounds what might be learned from collective conversations about issues profoundly familiar (in one way or another) to focus group participants. This function also highlights the dialogic nature of focus group interaction, as well as the possibility for transformative encounters (e.g., Freire, 1970; Morley, 1980). The goal of the *political* function of focus group work is advocacy and social change for social justice. This function alerts us to the sources of collective support that can be assembled in relation to social and political issues, as well as the dangers of naïve notions of collectivity (e.g., Behar, 1993; Dill, 1994; Espiritu, 1997; Madriz, 2000). The *inquiry* function of focus group work alerts us to deep epistemological issues and concerns around “the research act,” including the complex negotiations between “self” and “other” in inquiry (e.g., Lather and Smithies, 1997; Radway, 1984). Although one function is usually dominant in any given research endeavor, all three focus group functions are usually present to some degree, reflecting and refracting the content of focus group work in different ways (Fig. 4).

Although one function is usually dominant in any given research endeavor, all three functions are usually present to some degree, reflecting and refracting the content of focus group work in different ways. Moreover, these three functions are seldom related in simple, unproblematic ways. Political interventions, for example, do not necessarily emerge from inquiry, but in some situations, they might. Similarly, pedagogy is not always central to activist work, but it can be and often is. Within any given project, these different dimensions or functions of focus group work emerge and interact in distinct and often disjunctive ways, eventually resulting in some unique interactive stabilization.

Quasi-unique affordances of focus group research

All strategies for gathering information from research participants have different affordances—that is, any given strategy is likely to allow researchers to learn some things and not others or some things more than others. In this regard, Kamberelis and Dimitriadis (2011) noted that focus groups have some quasi-unique affordances compared to other data collection strategies. It is not so much

Fig. 4 Primary functions.

that they allow researchers to gather certain kinds of information that could not be gathered to some extent using other strategies; it is more that they are likely to allow researchers to generate more focused, richer, more complex, and more nuanced information, especially in relation to certain topics or domains of inquiry.

Some of the most important and powerful affordances of focus group work we have written about previously include (a) mitigating the researcher's authority, (b) leveling power relations among participants and researchers, (c) approximating the "natural," (d) backfilling gaps in understanding yielded by other data collection strategies, (e) drawing out depth, complexity, and nuance of the phenomena under study, (f) saturating understandings, and (g) promoting political synergy that can lead to social change.

Mitigating researcher's authority

Authority and control can lead to premature closure and weak standards of evidence. Focus groups offer the researcher unique opportunities to relinquish authoritative power, which often results in more and richer data, especially with marginalized populations and in relation to sensitive topics (Fig. 5).

A key exemplar of the power of mitigating the researcher's authority in focus group research is Hill's (2009) study of the ways complex personal and social issues were explored with high school students through the lens of rap and hip hop. Especially important here was Hill's extensive knowledge of rap and hip hop and how this knowledge paved the way for more equitable sharing between Hill and his research participants. We recommend reading this book to get a deeper sense of this affordance at play.

Leveling power relations

Focus groups also encourage leveling power relations among researchers and research participants, which usually allows researchers to witness something close to "natural" group dynamics, yielding data with considerable ecological validity (Fig. 6).

A key exemplar of leveling power relations among participants and researchers in focus groups is Duneier (1992). Duneier studied the lives and stories told by a group of African American (and some white) men who hung out together in a neighborhood eating establishment called "Valois" on the south side of Chicago in the late 1980s and early 1990s. Importantly, it took Duneier many months and many awkward quasi-conversations to finally build trusting relationships with his participants, after which

Fig. 5 Mitigating researcher authority.

hierarchical power relations began to erode and conversations became more authentic and more dynamic. We recommend reading this book to get a deeper sense of this affordance at play.

Approximating the “natural”

Although not entirely “natural,” focus groups can serve researcher purposes of approximating natural interactions when carefully designed. Focus groups have the potential to “create” naturalistic spaces for re-performing everyday knowledge and practice (Fig. 7).

Fine et al. (2004) *The Echoes of Brown Project* is an excellent exemplar of this affordance. This project involved working with scores of youths to investigate the “so-called” racial achievement gap from *their* perspective. When investigating this topic through typical academic means fell flat, Fine and her colleagues consulted with the youth about alternative investigative tools. Together and with community elders and local artists of various kinds, they adopted a more local, “oral history” approach to generating knowledge and a more “performative” approach to sharing what they learned—writing, directing, and producing a play of sorts “that brought together political history, personal experience, research, and knowledge gathered from generations living in the immediate and long shadow of Brown” (p. 33).

Disclosing eclipsed or invisible connections and backfilling gaps in understanding

Focus groups are particularly useful for revealing partially invisible aspects of phenomena under study and generating more complex, nuanced understandings of those aspects—either during focus group conversations themselves or by chasing down other data mentioned in these conversations (Fig. 8).

Martin’s (1995) book on the history of immunology in the United States is a great example of this affordance at work. By viewing immunology from the days of polio to the age of AIDS, through both the lens of scientific discourses of immunology and political-economic discourses of new capitalism allowed her to disclose perspectives that were counterintuitive and thus relatively invisible. And collecting data from many different kinds of people (e.g., scientists, political scientists, social activists, hospital patients) and in many different social spaces (e.g., laboratories, health care centers, neighborhood associations, support groups, block parties, community meetings) further helped Martin disclose and render complex, nuanced, and even polyphonic accounts of health

Fig. 6 Leveling power relations among participants and researchers.

and illness as a kind of social-cultural-racial survival of the fittest—an insightful characterization that required a complex theory-method assemblage to generate.

Drawing out complexity, nuance, and contradiction

Focus groups can be thought of as the “tip of the iceberg” when it comes to data collection. Conducting focus group research can help to remind readers to work against premature consolidations of data, thus signaling the limits of reflexivity (Fig. 9).

This affordance is especially visible in Fine and Weis’ (1998) work with poor and working-class Caucasian, African American, and Puerto Rican men and women in Buffalo, New York and Jersey City, New Jersey (See also Weis, 2005). These researchers were interested in how their research participants experienced and understood social problems like domestic abuse, the police, and equity in school. As it turns out, participants’ experiences and consequent understandings varied widely as a function of their intersectional identities (race-ethnicity-class-gender-etc.). Thus, these researchers’ findings about the focal issues of their study were more kaleidoscopic and indexical than focused and contained.

Saturating understandings

In many ways, saturation is the converse of indexicality, which we will discuss in the second half of this chapter (Fig. 10).

Fetene’s (2009) study of how young college students in Ethiopia understood HIV/AIDS is instructive here. Individual interviews suggested that government and media explanations about HIV/AIDS as rooted in an ignorance of safe sex practices were somehow off-base. Focus groups revealed that young people are acutely aware of such practices but actively resisted them for a variety of personal, social, and political reasons. Moreover, whereas his participants were reluctant to talk about sensitive topics related to sex and HIV/AIDS in one-on-one interviews, the floodgates opened when they are asked to discuss these same topics with peers in focus group conversations, which led to rich, relatively saturated understandings that challenged many status quo beliefs about childhood and adolescence, sex, condom use, and HIV/AIDS.

IF EVERYDAY INTERACTIONS THEMSELVES ARE PERFORMANCES, THEN FOCUS GROUPS CAN BE A WAY OF INVOKING AND ACCESSING THE VERY DYNAMICS OF THESE PERFORMANCES.

Approximating the "Natural"

Focus groups can afford a closer approximation to natural interactions than many other data collection strategies.

Focus groups have the potential to "create" naturalistic spaces for re-performing everyday knowledge and practice.

Fig. 7 Approximating the "natural".

DISCLOSING ECLIPSED OR INVISIBLE CONNECTIONS

BACKFILLING GAPS IN UNDERSTANDING

YIELDED BY OTHER DATA COLLECTION STRATEGIES

Researchers and their participants contribute to shaping the objects they study in the absence of extant models for contextualizing referents of research such as "the world system," "capitalism," "the state," "the nation," etc.

Focus groups can illustrate the myriad kinds of collective conversations that can emerge when interactions between researchers and research participants are not prefigured but emergent.

Fig. 8 Disclosing eclipsed or invisible connections.

Fig. 9 Drawing out depth, complexity, and nuance of the phenomena under study.

Promoting political synergy

Whether they are designed to do so or not, focus groups often promote political synergy among participants that often leads to political activist and advocacy work (Fig. 11).

Tuck's (2012) research on students who dropped out of high school but enrolled in GED programs to "repatriate" their school experiences and recover some sense of dignity is an outstanding embodiment of this affordance. Importantly, what these students revealed in focus group conversations was taken up by their school districts to create policies and practices that were less alienating to these students. This process, however, revealed some fault lines that threatened institutional stability of school buildings and districts in non-trivial ways. Largely due to the integrity of Tuck's research design and process, however, these buildings and districts were able to manage these threats without abandoning the positive change efforts they had created for students.

Summary

We have described each of the key affordances identified by Kamberelis and Dimitriadis (2011) and provided an exemplary research study that illustrates each of them. Like the three primary functions of focus group research, however, most studies make use of multiple affordances either explicitly or tacitly, and when designing any new study, it is useful to think of facilitation strategies that are likely to draw out as many affordances as possible.

Figured worlds of focus group research

Using Holland et al. (1998) trope of the "figured world" Kamberelis et al. (2018) introduced the idea that the forms and functions of focus groups vary considerably depending upon the ontological-epistemological grounding of the research study. According to Holland et al. (1998), figured worlds are culturally constructed, socially produced horizons for understanding and acting that recognize particular kinds of actors, assign certain meanings to specific acts, and value some outcomes over others. Put another way, figured worlds are cultural imaginaries constituted by "people like us" who think, act, desire, and use the same social and cultural tools toward similar goals.

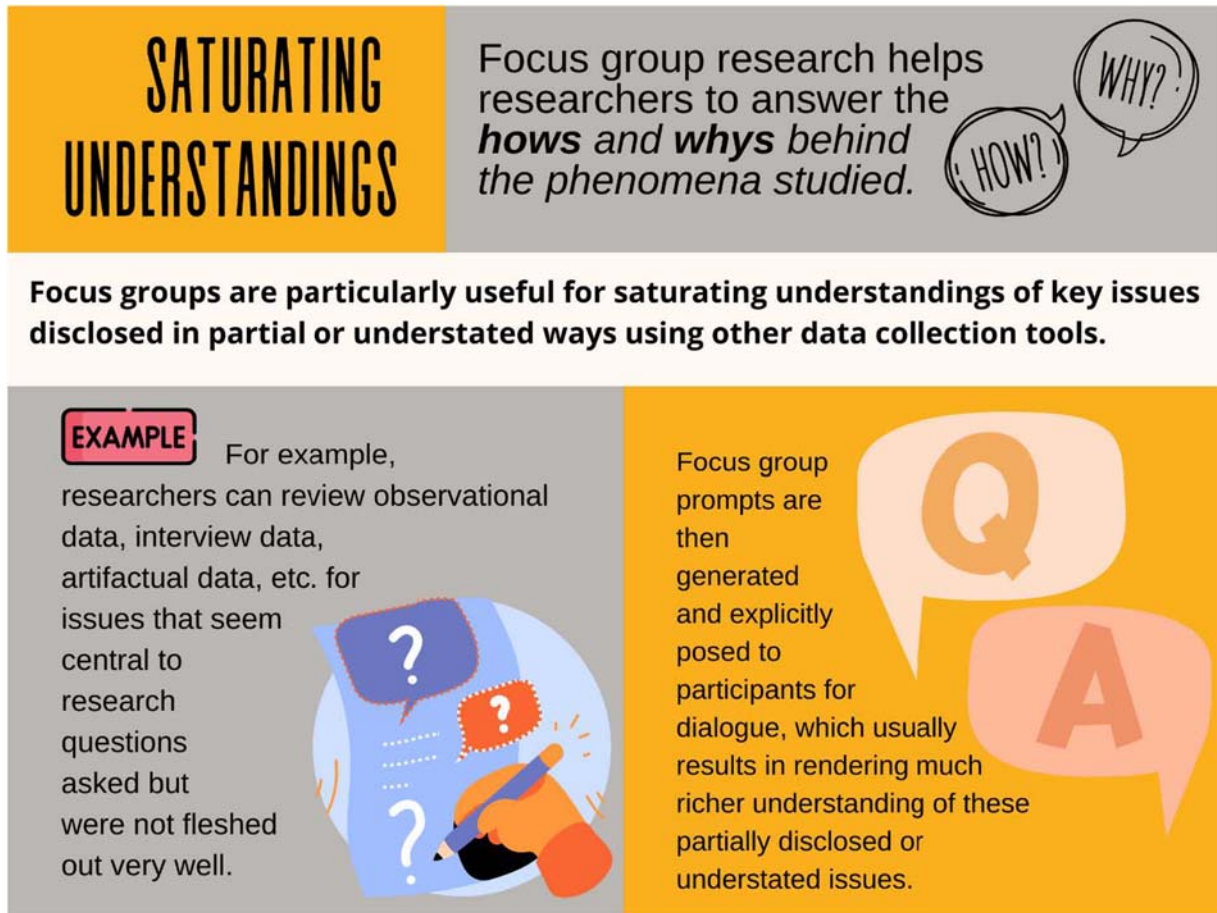

Fig. 10 Saturating understandings.

Fig. 11 Promoting political synergy that leads to social change.

George Kamberelis and Greg Dimitriadis have been cultivating the idea that there are multiple figured worlds of qualitative inquiry since their 2005 book *On Qualitative Inquiry*. In that book, they posited four chronotopes or figured worlds of qualitative inquiry. In Kamberelis et al. (2018), we added a fifth figured world of qualitative inquiry. Each figured world entails largely unique ways in which researchers think about the research process, use data collection strategies, and analyze, interpret, and explain information. Each figured world is complex and involves multiple, related assumptions. Chief among these are: (a) how knowledge and truth are construed, (b) what kinds of research questions are asked by whom and for what purposes, (c) how the relations between subjects and objects are thought about—including whether and how much agency different types of subjects and objects have, (d) whether and how reality is seen to be “brute data identifiable” (Taylor, 1979) or as culturally/socially/politically/economically produced (e.g., Foucault’s, 1977 “discourses”), (e) and how language and other cultural tools are thought about and used within each of them. Finally, as tropes or metaphors, figured worlds are more like topoi than surveyed plots separated off neatly in relation to each other. Additionally, each figured world leaks into, overlaps, faces off against, and/or slides into others.

Figured World 1

Figured World 1 is the figured world most of us leaned about in our high school science classes. It presumes a real world separate from and unaffected by humans. It also presumes that all knowledge of that world is discoverable. Through theory-making and hypothesis testing, the work of science is to represent that real world in ways that make it predictable and controllable (e.g., Boyle’s gas law, Piaget’s stage theory of child development, operant conditioning, $E = mc^2$). Like most modernist imperatives, the ultimate (and achievable) goal of the march of science is to discover and represent everything that is knowable about the objective world, which will presumably answer all human questions and end all human problems (Fig. 12).

Figured World 1 leans on facts and objectivism to provide quantifiable data for others to replicate. Such truths are meant to serve as “best practices” for the general population to follow and benefit from. Unlike the individual differences and affordances discussed in later figured worlds, Figured World 1 seeks statistical significance and verification.

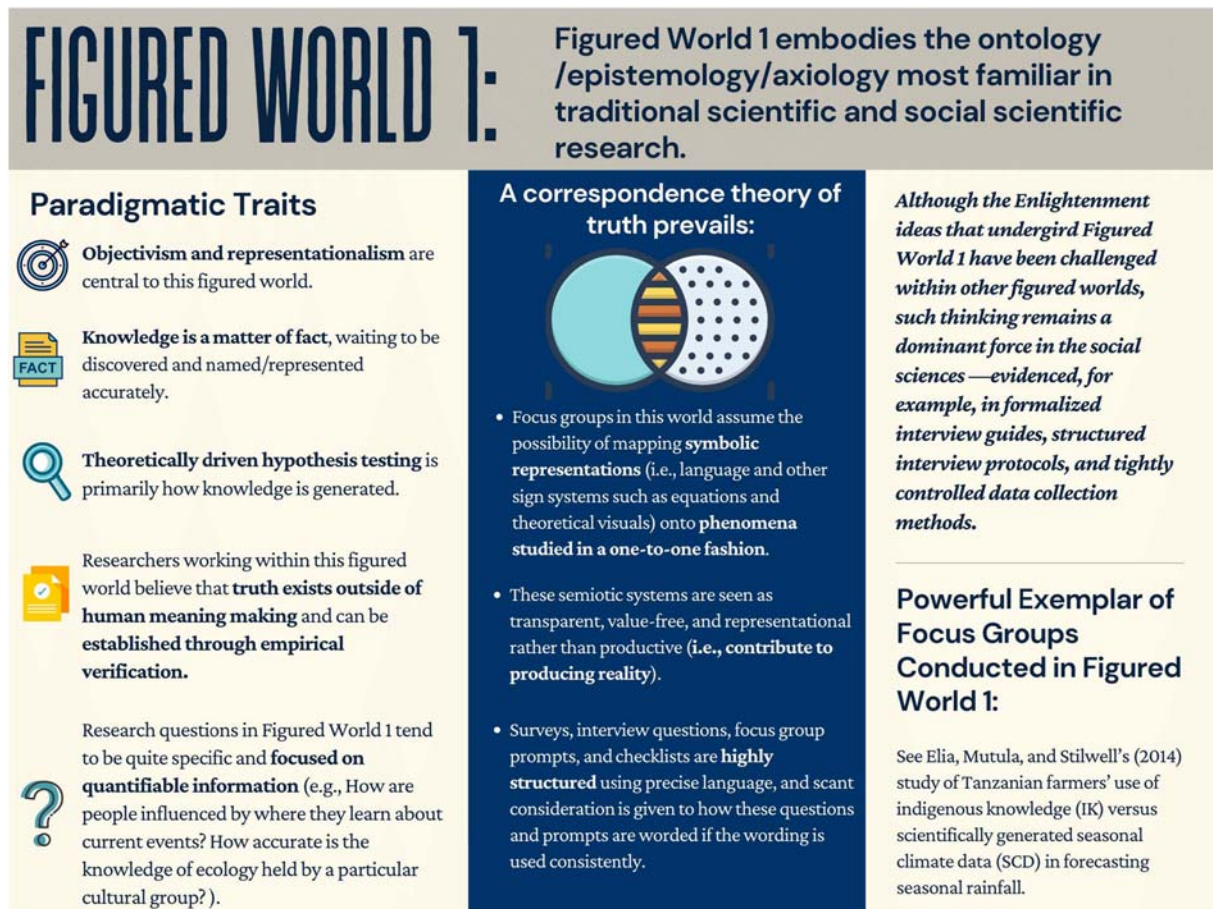

Fig. 12 Figured World 1.

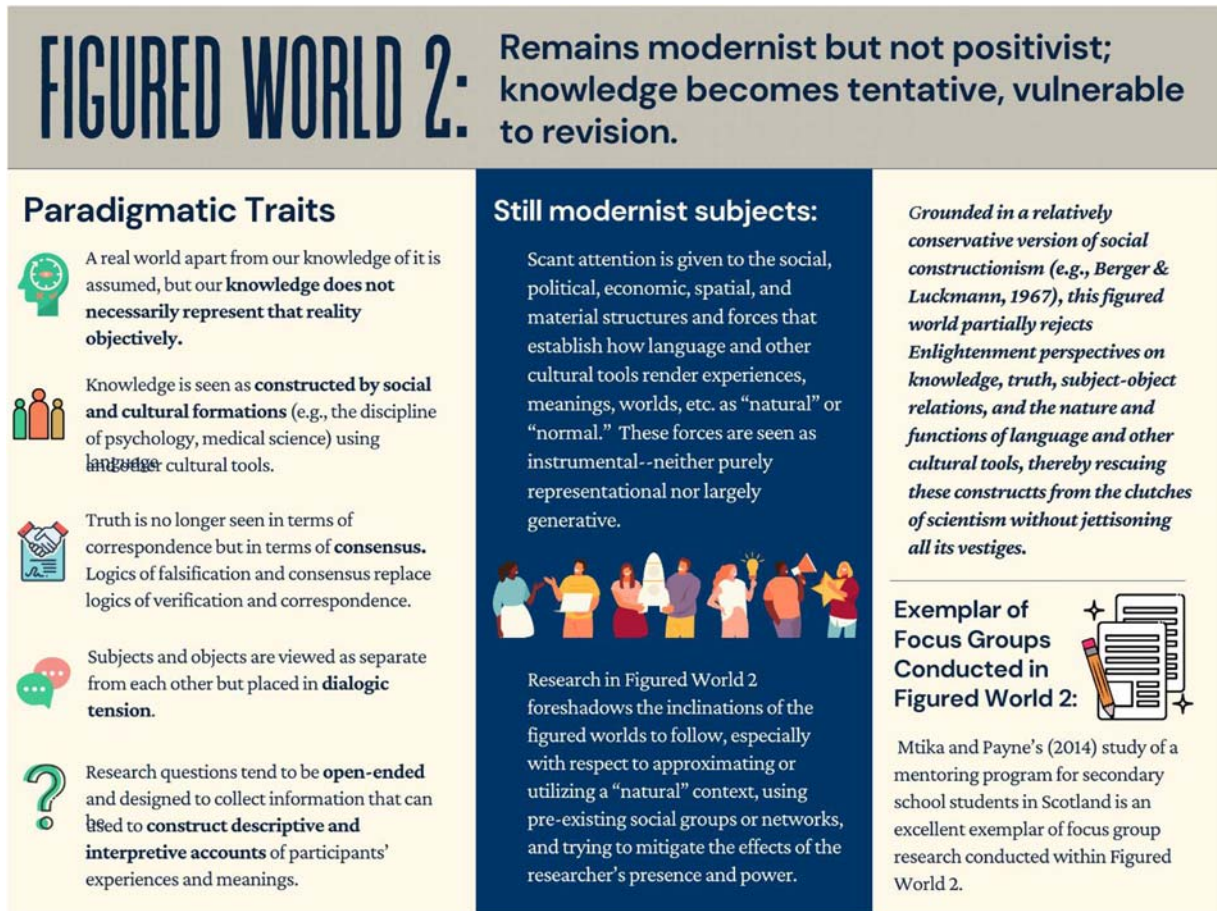

Fig. 13 Figured World 2.

Figured World 2

In Figured World 2, the constraints of scientism begin to loosen. Subjects and objects in Figured Word 2 are viewed as separate from each other but placed in dialogic tension, which is the hallmark of philosophical hermeneutics (the foundation upon which this figured world rests). Practices and meanings are understood in relation to the contexts in which they occur, and according to the principles of the hermeneutic circle where understanding parts of phenomena (a text, person, event, culture) always involves understanding the whole phenomenon (Fig. 13).

Because the goal is to understand people and their worlds, human subjects in Figured World 2 are still modernist subjects. These subjects have considerable agency to use the cultural (including scientific) tools at their disposal to construct themselves and to "discover" their worlds—even if they do not yet realize those worlds are always in the making. Unlike the more critical figured worlds discussed later in the chapter, the idea that knowledge and truth are effects of discourses (e.g., Foucault, 1977, 1988) is just emerging in Figured World 2.

Figured World 3

Figured World 3 is critical (e.g., Gramsci, 1971; Freire, 1970/1993) but not yet post-qualitative (e.g., Deleuze and Guattari, 1987; Rancière, 1991). In neo-Marxist terms, this is a matter of ideology critique, the goal of which "is to discern ... those 'ideologically frozen' relations of dependence that can be transformed only through critique. Thus, the critical approach is governed by the interest in emancipation, which Habermas also calls *self reflection*" (Ricoeur, 1992, p. 289). Habermas (1971) referred to this process as "emancipatory rationality," which is a mode of thinking/being that allows people to escape the lures of oppression through collective self-reflection. Social movements such as second-wave feminism and the civil rights movement exemplify how Habermas' rational, emancipatory, de/recolonization project has been historically enacted (Fig. 14).

Simply put, scholars working within Figured World 3 encourage people to engage in discursive practices designed to instigate change. However, the idea that researchers and research participants are also victims of language and discourse is not well developed, nor are other non-human phenomena seen as having agency. For instance, if electricity were introduced to a non-electrified geographic region, the people who brought the electricity and not electricity itself would be seen as agentic in people's lives. As we show later in the chapter, agency is viewed quite differently in Figured Worlds 4 and 5.

FIGURED WORLD 3:

Researchers become critical, co-investigators.

Paradigmatic Traits

This figured world is explicitly concerned with **questions of power**, especially how human activity is embedded in **hegemonic structures that reproduce existing structures of power**.

The goal is to **motivate social action that liberates people from the constraints** of extant ideologies about how they (should) think, feel, and act.

Researchers here assume that **surface-level meanings and actions hide embedded structural conflicts, contradictions, and fallacies** that maintain the status quo while hindering dialogic and democratic forms of life and their attendant practices.

The goal of all discursive and material activity in Figured World 3 is **praxis: the process of linking theory and practice to enhance the possibilities** of specific groups, thus improving the world

Reciprocal relationships must lead to common goals that express the **transformative possibilities of a dialogic community**.

Research questions are **emergent and open-ended**, typically inviting research participants to adapt these questions based on their own knowledge and experience before developing them further.

The path to knowledge:

- With emancipatory rationality as the path to knowledge, and with **knowledge seen to be socially/culturally/politically/economically constructed**, truth in Figured World 3 is a matter of consensus achieved through dialogue and debate in which reasoned argumentation, adequate evidence and warrants are all highly valued.
- **Discourses are treated more as objective facts** than as force fields that delimit what can or cannot be discussed, considered normal, and believed as true.
- Language and other cultural tools in this figured world are instrumental—used by people in dialogue to **deconstruct the conditions of possibility of their lives and to work towards different and better conditions**.

For the most part, the subject-object dualism central to Enlightenment thinking remains present (but is troubled). Individuals are still viewed as both rational and free, but these characteristics are impaired by a false consciousness induced by prevailing institutions of power. Therefore, rationality is no longer a property of the individual subject, but is instead best produced in unconstrained dialogue with others. This means that Figured World 3 is grounded in a social, rather than an individual, kind of idealism.

Notable Focus Group Work in Figured World 3:

See Baldissera, Bueno, and Hoga's (2012) action research on the sexuality of older adult women living in southwest Brazil.

Fig. 14 Figured World 3.

Figured World 4

Knowledge in Figured World 4 is viewed as an effect of power that is produced, reproduced, and transformed through discursive practices informed by discourses (Foucault, 1977, 1988). Therefore, researchers are (and should acknowledge) that they have been constructed within academic discourses that constitute filters through which they see and act in the world. Thus, getting in and out of the way of their participants becomes a key activity for researchers within these figured worlds, which illuminates the process by which voices of others are represented by juxtaposing narratives, counter-narratives, and metanarratives. Even more than in Figured World 3, agency in Figured World 4 is limited in that it is always already an effect of discourses (and not free will or individual intention). Because knowledge and subjects are both effects of discourse, agency has to do with deconstructing discourses and using them strategically (Fig. 15).

The characteristics and concepts guiding Figured World 4 require acknowledging that the research process itself is often riddled with contradictions. Constructs such as "giving voice" are neither "innocent" nor self-evident. Instead, they are named, troubled, and performed through talk, social interaction, and writing in ways that allow participants to re-imagine and enact possible worlds and possible selves.

Figured World 5

Figured World 5 is the most embryonic world on our heuristic landscape; it is thus "bricolage" par excellence—assembled from bits and pieces of philosophy and theory in intentional but not necessarily scientific ways. Yet that is part of the point, as truth is seen as both chimerical and an effect of hegemony. As in Figured World 4, language and discourse are seen as productive rather than representational. However, non-human and non-discursive forces— affect, esthetics, space, mobility, materiality, etc.—are also seen as agentic and productive, which means this work challenges the idea that the intelligible gets ordered and controlled primarily through language/discourse (Fig. 16).

Materiality is also a constitutive force in Figured World 5 as it involves the presence and organization of physical and/or digital materials that affect how social activity and work get done. Like materiality, space, spatial relations, and spatial mobility/immobility can be forms of agency in this figured world. Finally, Figured World 5 is fundamentally about the possible. Researchers and research

Fig. 15 Figured World 4.

participants typically work together both to deconstruct the worlds in which they live and to construct new worlds viewed as both possible and desirable.

Data collection and data analysis

Having introduced this “figured worlds” heuristic, it will not surprise readers that we encourage thinking about collecting and analyzing focus group data using a continuum model. In this section, we discuss the range of data collection and data analysis strategies common to focus group research located within different ontological/epistemological/axiological spaces (Fig. 17).

Collective conversations can be audio recorded and/or video recorded. Having video recordings of these conversations can provide a great deal more data for researchers to work with and learn from. In many of our studies, we have been able to see the meeting rooms where groups met, the facilitators stance and presentation, facial expressions, body language, what the weather was like that day, and even what participants were eating for lunch! All these visual elements provided insights that would have been lost had we only collected audio data.

Probably the most important factor in conducting focus groups and collecting focus group data is the positioning of the researcher. Three quasi-unique affordances of focus group research—(a) mitigating the researcher’s authority, (b) leveling power relations among participants and researchers, and (c) approximating the “natural” are instructive here, as are the various positions and positioning strategies implied in our discussion of figured worlds. Basically, focus groups conducted at the traditional end of the figured worlds continuum are typically tightly facilitated by the researcher with direct, highly focused questions, and conversations routinely unfold much like the initiation-response-follow-up (IRF) speech genre common in school classrooms. In contrast, focus groups conducted at the post-qualitative end of the figured worlds continuum are typically owned by and facilitated by the participants themselves after the researcher poses one or more open-ended prompts, and conversations are more likely to resemble those of coffee klatches or carnivalesque, multi channeled speech events (Bakhtin, 1981). Finally, focus groups conducted toward the middle of the figured worlds continuum fall somewhere between these two extremes.

Fig. 16 Figured World 5.

Although we understand the value of research located within the ontological/epistemological/axiological parameters of all figured worlds, because of the quasi-unique affordances of focus groups as data collection tools, we find the conversations toward the post-qualitative end of the figured worlds continuum to be most productive—both in terms of the richness of information gathered and the fact that more participant-owned, carnivalesque conversations are often transformative; they often disarticulate and rearticulate reality (Deleuze and Guattari, 1987)

Indexicality and its functions in focus group research

Based on experimental uses of focus groups in social science research during the past decade or so, we have added another quasi-unique affordance to the list we generated in Kamberelis and Dimitriadis (2011). Because focus group conversations are highly indexical (tips of icebergs), it is often advisable to chase down data indexed but not fully developed in focus group sessions. In a study of consuming and producing art (Welker and Kamberelis, 2021), for example, focus group conversations indexed (or pointed toward) artwork in the research site (a museum), art talks, students’ written reflections on exhibits in the museum, students’ art journaling, student-produced artwork, whole-class discussions about each students’ artwork, and much more. We collected and analyzed these data in relation to focus group data to produce our findings (Fig. 18).

What are all the things that we might learn about people, places, and naïve theories that are in maps such as this one? Indexicality is a fundamental research principle and should guide every step of the process. Imagining indexical potentials can begin before data collection and analysis even begins. We will talk more about how indexicality tends to play out in particular data collection and analysis activities in the second part of the chapter.

Analyzing collective conversations

How to analyze data from collective conversations, as well as other data indexed in these conversations is an important decision each researcher must make for any particular study. Just about any of the many common (e.g., grounded theory) and less common (e.g., rhizomatic analysis—a predilection grounded in the quasi-unique affordances of focus groups as information gathering tools,

Fig. 17 Data collection strategies.

especially their highly indexical nature) qualitative data analysis strategies/systems may be used to analyze focus group data no matter what figured world a study is located within. However, just like certain theory-method assemblages are more coherent and make more sense than others, some figured world-data analysis assemblages seem more coherent, commensurable, and productive than others. In the remainder of this section, we will provide several examples and counterexamples of what we view as optimized assemblages. These examples will be glib; we will not unpack the various analysis strategies/systems; we discuss; we will, however, provide citations for resources we think are especially valuable/useful. That said, previous literature has focused on more positivist, post-positivist, and/or constructivist analysis strategies; however, we are excited about the unique and uncharted territories of more critical and post-qualitative analysis tactics used in relation to collective conversation data.

Focus groups as data have a “unique identity” that is not “naturally occurring” but can be orchestrated to be very close to naturally occurring by taking advantage of the quasi-unique affordances we discussed earlier in the chapter. This tends to occur less when studies are situated within traditional figured worlds and more when studies are situated within more critical/post-qualitative figured worlds (Fig. 19).

The potentials of research using focus groups have continued to expand considerably, especially during the last couple of decades. There are many ways to collect and analyze collective conversation data. We have already confessed our predilection for more critical, post-qualitative forms of data analysis such as situational analysis and rhizomatic analysis. Still, given our figured worlds heuristic, we encourage researchers to use whatever analytic tools and systems seem to fit best with the ontological/epistemological/axiological spaces they occupy and the kinds of data they collect. In the remainder of this chapter, we discuss very recent focus group research orientations and projects that seem to push beyond even the most critical/experimental types we have discussed so far and seem to foreshadow things to come in the ever-expanding world of focus group research.

Prospect: a social-cultural-political imaginal of focus group futures

Our understanding of the social-cultural-political imaginal futures of focus group research has been developed in conjunction with Denzin and Lincoln's (2018) tenth and eleventh moments of qualitative inquiry. The tenth moment (2010–2015) is characterized

INDEXICALITY

As educators, we find that supplementing collective conversations with additional forms of data allows us to understand more about individual participants as well as their interactions within the group as a whole.

Additional data often include:

Fig. 18 Indexicality.

as “the fractured, post-humanist present that battles managerialism in the audit-driven academy.” The eleventh moment (2016–) is characterized as “an uncertain, Utopian future where critical inquiry finds its voice in the public arena” (p. 9). We believe the new frontier of focus group research is located within these moments, which is important because decades of struggle by many scholars and practitioners have brought qualitative inquiry to a point where “politically informed action research, inquiry directed to praxis, and social change (Denzine and Lincoln, 2018, p. 890) are now deep and abiding commitments worth continuing to fight for. In relation to these commitments, scholars who use focus groups in their research have been among the key trailblazers and are likely to continue to be (Fig. 20).

Additionally, we utilized Deleuze and Guattari’s (1987) work to help illustrate the unique developments we encountered as we reviewed recent literature that included elements of collective conversations within their analyses, which resembled but were not defined specifically as focus groups. To work with and to better understand these similarities and differences, we leaned on Deleuze and Guattari’s (1987) key distinction between “tracing” and “mapping” that is instructive for understanding the “break” or “turn” we believe is happening with respect to using focus groups in contemporary social science research. Deleuze and Guattari espouse an ontology of becoming(s) rather than being. Reality is viewed as a continual process of flux or differentiation even though this fact is usually masked by powerful and pervasive illusory discourses of fixity, stability, and identity that have characterized most of western philosophy and theory since at least the Enlightenment. This ontology of becoming(s) enables (even urges) us to see things differently—in terms of what things might become rather than what they currently are. This ontology is characterized by its ability to engage productively with real movements of social change that open new forms of life both for individuals and for collectives. Based on this ontology, a “tracing” is a copy and operates according to “genetic” principles of reproduction based on an a priori deep structure and a faith in the discovery and representation of that structure. Tracings are typically based on phenomenological experience that is assumed to be essential, stable, and universal. Defined thus, the findings from most research projects are tracings. In this regard, our 2018 Handbook chapter, we also worked to trace focus group research through specifically defined representations; however, we found that we were in need of additional strategies as our understanding of terms and definitions continued to expand.

Deleuze and Guattari’s construct of “mapping” emerged as especially useful. In contrast to “tracing,” “mapping” charts open systems that are contingent, unpredictable, and productive:

Fig. 19 Data analysis spectrum.

The map is open and connectable in all of its dimensions; it is detachable, reversible, susceptible to constant modification. It can be torn, reversed, adapted, to any kind of mounting, reworked by an individual, group, or social formation. A map has multiple entryways, as opposed to the tracing, which always "comes back to the same."

Deleuze and Guattari (1987, pp. 12–13).

"Mapping," when applied to focus groups conceived as collective conversations, allows for an adaptation of previous definitions and conceptions of focus group research, which we outline below.

Mapping alerts us to the need to look at discursive, social, and material formations in terms of their constitutive lines of force—their organization into lines of articulation and potential dissolution into lines of flight. This works against seduction by received models; it makes visible new possible organizations of reality; and it opens up new ways of organizing political resistance (praxis). Praxis-oriented research is research that offers up different ways of organizing reality so that new becoming(s) (both for individuals and for social formations) are possible.

In drawing maps, the researcher works at the surface, creating possible realities by producing new articulations of disparate phenomena and connecting the exteriority of objects to whatever forces or directions seem potentially related to them. As such, maps exceed both individual and collective experiences of what seems "naturally" real. Ultimately, mapping discloses potential organizations of reality rather than reproducing some prior organization of it.

"Mapping" the future of focus groups

So far in this chapter, we have engaged in "tracing"—sharing what is already known about the nature, functions, affordances, and uses of focus groups in social science research. In the remainder of this article, we shift to "mapping" focus groups futures. In this regard, we are not here to argue what focus groups are and what they are not. Nor are we here to claim that any belief/epistemology/discipline/paradigm/figured world, etc. is better than any other. Instead, we are here to share what we see as new lines of flight that

Fig. 20 Denzin & Lincoln's historical moments of qualitative inquiry.

can help us transverse/transcend the potentials of social science research in ways that play to Denzin and Lincoln's tenth and eleventh moment agendas.

Scholars using focus groups have previously tended to focus on the discursive or "talk data" produced by the transcripts of focus group conversations; however, we would like to redefine this discursive interaction to accommodate the subjective and performative intra-actions that create a renewed potential for asking and answering questions rendered all but invisible by traditional framings. Focus group research is now positioned to take us beyond patterned, rhythmic types of research (tracing in Deleuze & Guattari's lexicon) and into the unknown (mapping in Deleuze & Guattari's lexicon), which will shed light on how researchers might stretch how focus groups are conducted and what their purposes are. Such stretching includes cultivating more global conversations, especially given the power of such conversations to create confluences of peoples who may not know each other or have a shared agenda but what to come together to build new connections and new communities committed to co-constructing new knowledges with both scientific and political teeth. In other words, focus groups can be used to break free of the systemic, oppressive, and political failures of education (and other institutions and to discover/produce ways to think, act, and exist differently in the world ([Fig. 21](#))).

Many innovative, "post" focus group studies have been conducted during the past decade or so. We have selected three of them that have helped us expand our ideas about the potentials of focus group/collective conversation research ([Bass et al., 2020](#); [Kruger and Roux, 2017](#); [Yetiskin, 2020](#)). These studies showcase how focus groups are currently being used in innovative ways that utilize strategies and tools from the past while also integrating new and unique affordances that expand our previous notion of what it means to do focus group research. In this regard, some contemporary researchers don't even use the term "focus group," but, their work is clearly about collective, meaningful interactions among human beings around issues that are compelling to them ([Figs. 22 and 23](#)).

More importantly, these three studies provide exciting examples of the "becoming(s)" of focus group research that break from tradition to extend the questions asked and the meanings found within the evolving nature of educational research and social science research generally. Although the first and earliest study was conducted by educators within departments of education, the other two examples are more interdisciplinary, integrating ideas and practices from multiple social science and humanities disciplines. From these three studies (and other studies that have widened the parameters of focus group research), new affordances have been brought to light.

"FABULATION AS A PEDAGOGICAL POSSIBILITY: Working Towards a Politics of Affirmation"

Frans Kruger & Adré Le Roux

FINDINGS

Kruger & Le Roux's work is mostly theoretical. Although they discuss what this pedagogical shift has taught them, the researchers do not provide specific examples or empirical data. Additionally, it is important to note that Kruger and Le Roux do not use the term "focus group" in their work, but we find extensive parallels between fabulative conversations and focus groups oriented within post-qualitative worlds.

Kruger and Le Roux struggled to create social-justice-oriented pedagogies for their first-year, pre-service teachers. They observed that their past attempts at creating space for such conversations in the classroom often led to a perpetuation of a politics of negation.

The authors found that engaging students with fabulative conversations allowed them to experiment with a politics of affirmation, which provided opportunities for students to break away from intergenerational stories, hegemonic histories, and identity politics.

Further, these fabulative conversations were facilitated by instructors who intentionally devalued received truths and realities in favor of working collaboratively to create new perspectives and acknowledge the ever-present process of becoming.

Fig. 23 Frans Kruger & Andre Le Roux's research (study #1).

Brief summaries of the studies

Study 1

Kruger and Le Roux (2017) conducted a study in post-Apartheid South Africa with the aim of "enabling 1st-year pre-service [education] students to critically challenge their own identities in a diverse world by imagining the possibilities that exist for social responsiveness as agents of change" (p. 47). Kruger and Le Roux are clear about how important the historical context of their work was; their students held involuntary memories grounded in a hegemonic past. These memories varied depending on who was telling the stories of the past, what they had at stake, and whether the Apartheid was something that a person was harmed by or benefitted from.

Additionally, Kruger and Le Roux's student participants were living at a time when political and racial protests were occurring, such as the 2015 Rhodes Must Fall protest at the University of Cape Town. The national crisis indexed by such events prompted the need to create transformative spaces and thus redefine the moral responsibilities of university-level educators. The authors thus engaged in work to uncover opportunities for students and teachers "to break from the intergenerationally received stories and hegemonic histories through counter-actualizing regulation of difference through identity politics" and "to move from understanding social justice and pedagogical practices premised on a politics of identity and negation toward experimentation and a politics of affirmation" (Kruger and Le Roux, 2017, p. 49). Kruger and Le Roux's students were able to share their experiences, their stories, their families' stories, and stories they had heard from other students in the class who had both similar and different experiences and stories. This varied collection of stories created a wider, more expansive meta-narrative that was more inclusive and socially just. Key findings from this work are presented in the figure below:

In sum, Kruger and Le Roux staged collective conversations with a unique group of students in their education courses. The authors suggest that other educators can do this too, with similar and different topics of conversation depending upon the experiences, location, and historical moment each group exists within. Researchers collecting data in this way are not hoping for specific outcomes; instead, they are on the lookout for transformative potentials of data as they come into being.

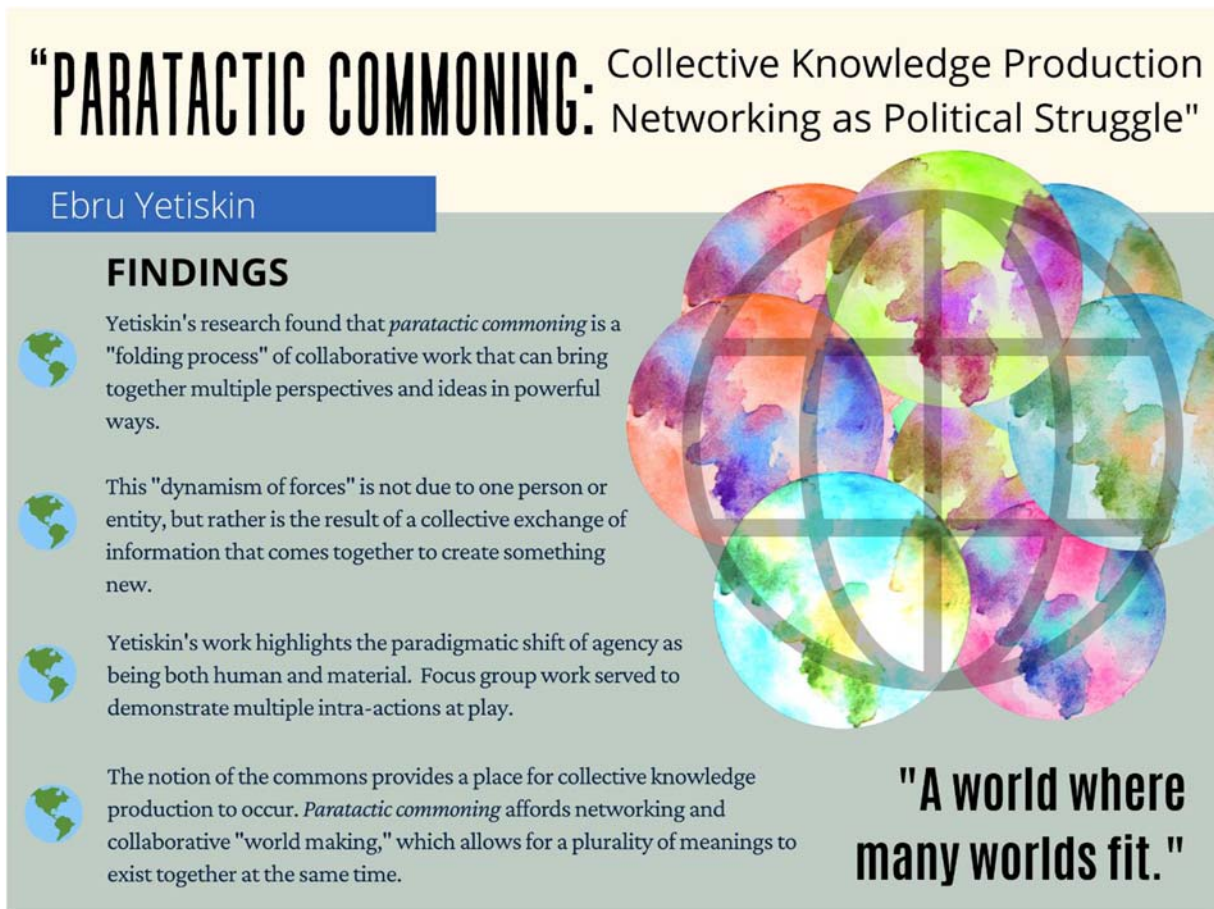

Fig. 24 Ebru Yetiskin's research (study #2).

Study 2

Yetiskin (2020) designed a study inspired by the civic data initiative: *Networks of Dispossession* (Adanali et al., 2013-present). This is an ongoing data-gathering initiative that works to collectively network and map exploitation of capital and power in Turkey. The construct that motivated this work is the "commons," which "are basic rights for accessing, using, and managing shared resources (i.e., data) in collaborative, distributed, and nonproprietary ways" (Yetiskin, 2020, p. 2). Using discourses about the Coronavirus pandemic as an example, Yetiskin demonstrated how the commons can be manipulated (even co-opted) by networks of the state and/or powerful corporations, which can lead to issues with transparency and accountability. In such cases, "power is ... centrally exerted by automating and regulating what *can* be accessed, transacted, processed, stored, understood and known in the public" (Yetiskin, 2020, p. 2). The primary purpose of Yetiskin's research was to learn how strategies of "paratactic commoning," may be used subversively to counteract this use of power. Paratactic commoning is a commoning practice where commoners collect and disperse public data as means for exploration, disclosure, and subversion to create and share alternate ways of knowing. Yetiskin uses focus groups to learn more about the potentials of paratactic commoning, which is similar to the general post-qualitative use of focus groups for exploring and redeploying tactics of power and control in ways that reveal and subvert such workings. "Thus, paratactic commoning can be practiced within proactive and subversive interventions of self-organized, self-reflexive, and self-aware networking assemblages that defend the rights to access, use and manage commons collectively and pluralistically" (Yetiskin, 2020, p. 2). In this sense, paratactic commoning becomes an on-going, online, asynchronous type of focus group where data may be extracted in invariable ways at various points across time for multiple research purposes by multiple researchers. The figure below was designed to outline some of the potential affordances of paratactic communing as a focus group variant researchers might enact in their current and future work (Fig. 24).

These subversive "commoning practices also take back control of redistributing power to take care of 'response-ability' of commons as well as commoners" (Yetiskin, 2020, p. 2). Driven by a commitment to global social change, Yetiskin pushed the usual limits of paratactic commoning further by distributing the ideas generated by her students on a larger scale (e.g., international conferences, peer-reviewed articles, etc.) These dimensions of her work "validated 'how' limited voices and partial sights in various parts of the world can be linked, mediated, and multiplied within skilled practices of commoners to co-produce situated knowledges and unexpected openings in contemporary political struggle" (Yetiskin, 2020, p. 5). Yetiskin imagines a world where local

groups engage in situational paratactic commoning as they work collectively to (re)distribute power, access, and information in more equitable ways. Further, Yetiskin hopes that small, paratactic commoning groups will work together with larger paratactic commoning groups to share information, help one another, and learn from each other, which would extend the global reach of such work.

Study 3

Bass et al. (2020) focused their research on migration scholars and the universities and other institutions that fund their work. These scholars noticed that faculty and students of humanities and philosophy viewed the “imperial eyes” of the academy as setting “the terms and limitations on interactions, locations, and relationality in research,” and they wondered whether this regime reduces “the agency of migrants” and produces “stratified configurations in the positionality of both migrants and researchers, and subsequently, exacerbate[s] [the] dynamics of exclusion and extraction” (p. 147). Influenced by scholars on the “frontlines” who resisted various manifestations of violence and exclusion, Bass, Córdoba, and Teunissen developed an approach to migration studies that “undermines the ongoing impact of colonialism and the normativity of institutionalized, hierarchical narratives that haunt academia” (p. 147). This study is particularly interesting in relation to Yetiskin’s research because the authors were working subversively in an attempt to “model a research design that takes tools from the research institution (e.g., funding, infrastructures, methodological frameworks) and uses them for liberatory purposes” (Bass et al., 2020, p. 148). Because these researchers received their funding from the European Union-funded Horizon 2020 Project, they were concerned their work might be used as “an instrument for migration management within the colonial context of European migration (Gutiérrez Rodríguez, 2018; Saucier and Woods, 2014)” (p. 148). To mitigate this threat, they “use[d] collective self-inquiry to undermine the academy’s imperial eyes, which produce stratified configurations in the positionality of migrants and researchers, while exacerbating hierarchies within the university” (Bass et al., 2020, p. 148). Collective self-inquiry is a matter of researchers with similar dispositions, interests, and commitments self-forming collective conversations both to critique/deconstruct their work and to refine their tactics for engaging in socially transformative work through shared dialog (Fig. 25).

Bass, Coroba, and Teunissen’s research demonstrates how focus group facilitators can fold and turn inside-out focus group activity so that researchers in collaboration with others studying both similar and different topics can become hyper-self-reflexive about their work. When using conversations for this purpose, we can see new affordances for focus group research—ones that expand the potentials for learning and being human in yet-to-be-imagined ways.

Focus groups as tools of subversion

Fabulative conversations, as described in Kruger and Le Roux’s (2017) work, are defined as imaginative spaces of creation and production. Such conversations allow participants to collectively invent their ideas of self and others as they acknowledge the continual becomings of individual and group identities. The authors explain that “group-subjects are transgressive because they subvert pre-established social relations, thus an identity based on involuntary memory and a hegemonic past” (Kruger and Le Roux, 2017, p. 53). These transgressive potentials are not possible without collective commitment and a facilitator who ontologically guides the participants through this work. Although Kruger and Le Roux do not call such fabulative conversations focus groups, their resemblance to focus groups can help us see how facilitators can guide the “ethico-onto-epistemology” (Barad, 2007) of a group to work past historical and social divides and attempt to create new realities.

Yetiskin’s (2020) work on potentials of paratactic commoning to interrupt and redirect flows of power and undermine strategies of prediction and control is another good example of how focus groups can be used as tools of subversion. Although Yetiskin does not refer to her work as focus group work, “paratactic commoning” bears a strong family resemblance to focus group research. This resemblance suggests that we may be helpful to expand our definitions of focus group work to include the various affordances and constraints that can be drawn via lines of flight across the spectrum of focused groups—collective conversations (Kamberelis and Dimitriadis, 2013) as tools for social transformation for increased diversity, equity, and inclusivity. Advocates of paratactic commoning argue that researchers must approach their topic as practice. This turn to practice can be used to challenge methodological symmetry when rethinking commoning across local settings perceived to be similar. Yet, ideas generated in one setting would not necessarily be generalized to others (except perhaps analogically), and such ideas would not preempt the analysis of how commoning is practiced differently in different socio-cultural settings. Paratactic commoning is thus a matter of co-producing “situated knowledges” (Haraway, 1988) and thus lived reality itself (Yetiskin, 2020, pp. 2–3).

What Yetiskin calls “tactical control of the commons” is similar to early focus group work such as Merton and Lazarsfeld (1968), where data were used to make predictions about citizens’ feelings toward war efforts. This research was intended to help researchers learn how best to persuade the masses to take a particular stance in relation to certain efforts related to the war. This use of power to influence public opinion is a type of control clearly has ethical implications that, taken to their extreme, result in fascism. Yetiskin’s paratactic commoning is one way of using focus groups to disclose and subvert this type of control.

Bass et al. (2020) highlighted the potentials of focus groups as tools of subversion as well. Although funded by the European Commission to conduct research on “migrants and their movements,” this group of doctoral students wanted to push against “imperial eyes” and the sedimented power of the academy. To do so, they appropriated and redeployed tools from the academy and related organizations (e.g., funding, infrastructures, methodological frameworks) for liberatory purposes—to undermine the academy’s imperial eyes (Fig. 26).

"(RE)SEARCHING WITH IMPERIAL EYES:

Collective Self-Inquiry as a Tool for Transformative Migration Studies"

Madeline Bass, Daniel Córdoba, & Peter Teunissen

FINDINGS

Using collective self-inquiry as a strategy, allowed these three researchers to look at their separate research projects reflexively and critically to address areas in need of improvement. From these reflections, researchers were able to see that, although their goals were clear, their actions needed to be further developed to push back against hidden imperial tendencies.

- Córdoba shared experiences of squatting with migrants as both an activist and later as a researcher in Barcelona. Córdoba collaborated with non-academics who expressed their distrust of the academy, which they viewed as serving capitalist agendas that were bound by domination and inequality.
- Córdoba's research aimed to create "beneficial and mutually enriching relationships" between the researcher and participants. Although Córdoba was unable to move the research beyond accepting differences and sharing storied experiences at the time, collective self-inquiry with Bass and Teunissen allowed for the generation of ideas for future transformative research.

- Teunissen's research involved traveling to the Greek/Turkish borderland in 2018 to demonstrate solidarity and support for the 'migrant/refugees' who were being detained. At the time, Teunissen was working with a group of volunteer activists and scholars to document the violence and deportation of Turkish citizens.
- Through this (re)searching and collective self-inquiry project, Teunissen was able to reflect on this past work to see that even though the goal of fighting against the violence at the border had been fulfilled, the research lacked a personal relationship with the migrants themselves.
- In the micro-focus groups that followed, Teunissen was able to see that forming personal relationships would have allowed the research to humanize migrants and refugees in ways that most research does not, as migrants are often rendered objects of research rather than subjects.

- In 2016, Bass taught 9th grade while completing graduate studies in sociology in a small village in Ethiopia. Although this was not an official research project, Bass was placed in a position of privilege when riding in a taxi with a local. Having both been removed from the same village due to violence in the area, Bass was able to work with, care for, and cry alongside this community member in a way that researchers should strive to do with their participants.
- Through re(search) reflections with Córdoba and Teunissen, Bass acknowledged that sharing feelings and stories with participants is an important first step, but never the last step in participatory action research.
- Action potentials such as "buying back an acre of settler land" could be enacted to build more socially just realities from these storied experiences.

Fig. 25 Bass, Coroba, & Teunissen's research (study #3).

Fig. 26 Focus groups as tools of subversion.

Widening the definition of focus groups: fabulative conversations, paratactic commoning, and collective self-inquiry

Drawing on autoethnographic, duoethnographic, and multivocal ethnographic research practices, Kruger and Le Roux (2017) developed a tactic they adapted from Deleuze and Guattari that they call "pedagogical fabulation" to engage students in fabulative conversations to "provide the opportunity to disentangle from the 'gravitational pull of established identities and practices that unnecessarily limit the question of how life might be composed'" (Kruger and Le Roux, 2017, p. 49). The affordances of fabulation allow students to imagine futures that do not yet exist in a way one might write a fictional story, pushing the normative concept of the "real" into the background to allow collectives "to experiment with the emergence of different future-orientated socio-political collectivities that a different way of thinking about our pedagogical practices could make possible" (Kruger and Le Roux, 2017, p. 50).

Fabulative conversations create spaces for reassessing and negotiating the way things currently are and the various ways in which reality is always changing and becoming something new. "Transformative potential of social justice pedagogies infused with fabulation subsequently lies with the collective action of becoming-other through the creation of a shared present" (Kruger and Le Roux, 2017, p. 57). Fabulative conversations bring together unique groups of learners who may not otherwise have interacted with each other. Their repetitive sharing of experience presents unfathomable opportunities that would not otherwise have occurred.

Kruger and Le Roux feel strongly about the nature and place of identity politics in the classroom and "how the centrality of identity politics ... not only perpetuates the notion of identity as being stable, self-contained and constituted through the process of negotiation, but that it feeds into a continued positioning of ... students on different sides of historical and social divides" (Kruger and Le Roux, 2017, p. 53). These scholars also believe that fabulation in the classroom can allow for greater creativity regarding social justice pedagogies that aim to enable students see beyond polarities to construct new perspectives and possible becomings (Fig. 27).

In sum, Kruger and Le Roux's main purpose of bringing fabulation into the classroom was to help their students (and themselves) imagine and create worlds that had not previously existed. Although the authors acknowledge that "such a future cannot be predicted nor its justness assured" (p. 51), they still feel that it is worth trying and has the potential to create a better world than the one in which they/we currently live.

Fig. 27 Working toward a politics of affirmation.

Yetiskin's (2020) theory of paratactic commoning works to expand the notion of focus group research and the myriad intractions that constitute data when social collectives are involved. Traditionally, focus group research has been conducted locally and synchronously, but Yetiskin's concept of paratactic commoning allows us to think of focus groups as collaborating across time, across space (both physical and virtual), and without a designated facilitator. These groups still share interests and stakes as they work to expose flaws, create connections, and construct new knowledge that can help themselves and others (Fig. 28).

Occupying researcher, participant, and facilitator roles simultaneously, Bass, Córdoba, and Teunissen's "collective self-inquiry" focus group variant involves conversations about migratory experiences with the goal of exploring "the academy's potential for liberatory practices through the development of alternative methodologies which emphasize community, affinity, and shared knowledge" (p. 149), thus "challenging the normativity of institutionalized, colonial narratives, and the 'b/ordering' of movements(s) of people across former empires" (Bass et al., 2020, p. 148).

This "messy" work "serves to clarify not just the end result of collective self-inquiry as a practice, but also, in a very practical sense, to elucidate the ways in which the process was carried out and the passionate, sometimes messy backstory behind collective work" (Bass et al., 2020, p. 149). All in all, this work foregrounds the academy's potential for liberatory practices through the development of alternative methodologies that emphasize community, affinity, and shared knowledge (Fig. 29).

Using focus groups to promote and sustain global conversations

Kruger and Le Roux (2017) worked with their students to engage in both local and global conversations, and their examples of classroom pedagogies can benefit educators and focus group researchers alike. Additionally, their work can serve as an example for anyone looking to have productive and critical conversations across lines of difference and polarization. Kruger and Le Roux explain that to have such difficult conversations, a facilitator with a Deleuzian/post-qualitative ontological perspective can help to keep the conversation on the path of the imaginative and to avoid received truths or returning to places participants have already been. "Such a resistance, which is contingent and specific, is a hope for a better future" wherein "the counteracting of preestablished truths occurs through the invention of a collectivity that does not yet exist" (Kruger and Roux, 2017, p. 51).

Among other things, Yetiskin extends these ideas in the interest of generating a global politics of knowledge production and the basic rights to access and management of shared resources. In this regard, recall that paratactic commoning is a commoning practice that uses publicly available data collected by commoners to "explore, reuse, reveal and subvert" tactically obfuscated facts by creating alternate visions and sharing them globally through Internet outlets, media outlets, conference presentation outlets, and publication outlets that are part and parcel of contemporary network cultures. Thus, paratactic commoning can be practiced by "self-organized, self-reflexive, and self-aware networking assemblages" with proactive and subversive intentions to defend the rights to access as well as use and manage the commons collectively and pluralistically. Yetiskin hopes this work can lead to new

Fig. 28 "Post" focus groups vs. paratactic commoning.

knowledge and explorations through producing new types of evidence, which can lead to fact-checking across a variety of global resources and references.

Bass et al. (2020) research was also designed to promote social justice agendas globally. Recall that they recruited research participants and gathered data gathered from three different locations: Barcelona, Ethiopia, and the Greece/Turkey border. With widely

Fig. 29 (Re)searching: collective self-inquiry.

Fig. 30 Using focus groups to promote & sustain global conversations.

varying lived experiences, these researchers also conducted a meta-analysis of their past studies. This work demonstrates how researchers across the globe can engage together in collective conversations, collective struggle, collective problem solving, and collective activism. Additionally, because these authors chose to publish under a Creative Commons International License, not only did they engage in global conversations, but they did so in front of a global audience, which increased access to and extended the reach of their work (Fig. 30).

Final thoughts: focus groups as tools for interdisciplinary, critical, global explorations

We began this chapter promising a more prospective (rather than a more retrospective) account of how focus groups are/can be used in educational research. We think we delivered on that promise. That said, we want to reiterate that focus groups are amazingly versatile information gathering tools that may be deployed productively across the entire figured worlds spectrum we described, as well as beyond the boundaries of that spectrum, which we tried to demonstrate in the second half of this chapter. In this regard, even though we are inclined to privilege more experimental, transformative uses of focus groups, we in no way believe that others should share that inclination. Focus groups remain powerful data collection tools for all kinds of research—from studies grounded in positivist epistemologies to studies grounded in post-qualitative ontologies/epistemologies to whatever comes our way next.

In the remainder of this chapter, we would like to offer some final (mostly forward-looking) thoughts on what we see as current frontiers of focus group research, especially in relation to the new affordances we discussed. Indexicality is especially important in this regard because it underscores the power of integrating focus group findings with other kinds of findings (e.g., field notes or other means for capturing observations, individual interviews, artifacts of various kinds, archival data) to produce far richer, more complex, nuanced understandings of phenomena under study.

The other affordances we proposed here—tools of subversion, spaces for collective struggle, and promoters of global conversations—align beautifully with the commitments of Denzin and Lincoln's tenth and eleventh moments of qualitative inquiry. Recall that the tenth moment is post-humanist and committed to challenging the hierarchical power relations of the academy and beyond to imagine and produce future-orientated socio-political collectivities designed for social justice. Also recall that eleventh moment is

characterized as “an uncertain, utopian future where critical inquiry finds its voice in the public arena” (Denzin and Lincoln, 2018, p.9). Thus, Yetiskin’s “paratactic communing” Bass, Córdoba, and Teunisson’s “collective self-inquiry,” and Kruger and Le Roux’s “pedagogical fabulation” are all tactics that embody the commitments of the tenth and eleventh moments.

Paying attention to the language used by contemporary scholars who are pushing the boundaries of focus group research, three constructs emerge as crucial, especially in terms of moving from engaging in research that privileges “mapping” over “tracing,” all the while acknowledging that all research usually deploys both to some extent. These three constructs are “intersect,” “transverse,” and “transcend,” all of which are central to thinking about post-qualitative modes of research inspired by theorists like Deleuze and Guattari (1987) and Barad (2007). Additionally, they are central commitments of much contemporary qualitative research (and especially post-qualitative research) designed to produce social-cultural-economic-political realities that are more diverse, equitable, and socially just on both local and global scales (Figs. 31 and 32).

In this regard, foregrounding affordances (especially the four new ones we introduced) was strategic in relation to these constructs. Affordances usually co-exist in all research projects and how they interact with each other is usually quite complex—intersecting, transversing, and mutually reinforcing each other in ways that are often transcendent. Additionally, foregrounding the notion of affordances underscores the expansive and ecumenical definition of focus groups that we have tried to develop throughout this chapter. Whereas most discussions of focus groups have, in effect, defined them a priori, we have done something different. We have emphasized neither the “typical” form or size of focus groups nor the procedures for conducting them. Instead, we have emphasized their potentials: (a) how they can serve pedagogical, political, and inquiry functions, as well as combinations of these functions; (b) their potentials for unearthing rich data sets that most other data collection strategies do not afford (or afford as well), and (c) how they can transform the lives of participants and the environments in which they live and work. Finally, based on our review of the literature and our own research experience, we are confident that the affordances we have discussed here emerge much more often and in more powerful ways in focus groups compared to most (perhaps all) other data collection tools. Why focus groups draw out these affordances in unique and uniquely powerful ways seems related to how performative they are and how the performances they spawn recapitulate naturally occurring social activity.

We have also drawn attention to exciting theory and research produced in recent years that suggests reimagining focus group research looks something like this: Non-positivist theories of truth reinforce the idea that the march or science is always a tentative march. Thus, how we understand the nature and functions of focus groups is always changing. In 5 or 10 years from now we will understand them yet differently, maybe with more complexity or nuance, maybe within a new and unforeseen paradigm shift.

Through our examples and figures, we have tried to show that focus groups (by any name) are being used in exciting, transformative ways across the globe and that these uses are opening up new potentials for what research means, how we do it, and what effects it may have. In other words, we inhabit a historical moment when Deleuze and Guattari’s call for “mapping” rather than “tracing” resonates more powerfully than ever. This is brand-new territory; we are not sure how to traverse its topological landscape; we do not know what we will find around the next turn; but we remain committed to mapping it as best we can. As fellow explorers, we offer the following advice to you:

Fig. 31 Intersect, transverse, & transcend.

What is naturalistic about “naturalistic observation”? Although a method of social inquiry, located within contested academic discourses, it is also something we do all the time, in our everyday lives, without necessarily remarking upon it unless, of course, we are caught and accused of being “nosey”. “Are you looking at me?” can in certain situations be not so much a question as a threat; or, perhaps a seductive provocation. We have, in many circumstances to “keep our eyes open”, “have our wits about us” to avoid dangers. Or, simply, to “keep aware” to know what is going on, in order to participate, to contribute our views to a situation, to recognize others and be a part of a community. In all its forms, whether as something we do as a part of everyday living, or as part of a research project, “naturalistic observation” is highly complex, sensitive, and often problematic yet necessary to our social existence and identities. The question then is, how do we make sense of what we are continually observing? And how do we know what we think is going on, is actually going on?

Observation

Observation seems to imply that the something that is “going on” can be seen, that we are in effect looking at or for something “seeable” or in more generalizable terms, “perceptual” or indeed “intuitable” in ways that are describable. However, perhaps what is going on, is something we are not looking at, or cannot look at. Perhaps then, the first move in naturalistic observation is to reflect upon what is “natural” to our own habitual patterns of attention and inattention. For example, in the experiment by Chabris and Simons (2010) students were asked to count the number of times a basket ball was passed between players. This they duly did. Then they were asked if they had noticed the gorilla. Few did. Yet a person dressed in a gorilla suit had passed among the players as shown by a replay of the video taken. In attending to counting, they were unable to notice the “gorilla”. What we perceive to be as “the natural world out there”, the “reality”, is constructed by patterns of noticing and of not noticing.

This of course, is a laboratory or at least a laboratory-like experiment that disturbed or at least made visible something about the role of attention in “seeing”. However, there is a distinction to be called between the experimental method and the naturalistic method. The idea behind the laboratory is to refine and reduce complexity in order to permit the control of variables so that through the variation of one variable, while holding the others constant, the effects that result can be attributed to it. This reduction to measurable and controllable variables is often referred to as positivism. However, the natural environments of the world outside of the highly specialized settings of the laboratory are not in anyway so controllable. As Cohen very early on pointed out in the case of using statistical sampling in the social and psychological sciences:

In the end, the truth of a generalisation from a sample depends on the homogeneity of the group with respect to which we wish to generalise. A single experiment on a new substance, to test whether it is acid or alkaline, is much more convincing than the result of a questionnaire addressed to millions of army men to measure their intelligence. For the latter is not a simple quality of a uniformly repeatable pattern. In this respect the methods of social statistics are gross compared with refined analysis, so that when our analysis is thoroughgoing, as it generally is in physics, one or two samples are as good as a million. If what we are measuring is really homogeneous, one is sufficient. In the social field, therefore, statistics cannot take the place of analysis ...

Cohen (1944:134–5).

Analysis in the natural world, or perhaps it could be called the wild world, has complexity as its irreducible feature. How do we accomplish analysis in such naturalistic settings?

If such settings are to remain “naturalistic” then presumably they should not be “unnaturally”, or artificially disturbed. However, there is little, if anything that the human does that is not “artificial”. As Agamben (2009) put it in his exploration of the Foucaultian use of the term “dispositif” (usually, albeit inadequately translated as “apparatus”), the dispositif includes language, discourse, tools, forms of organization, material and cultural infrastructures—in short, anything made or used by humans. A dispositif can be generalized to encompass the material and symbolic resources that can be called upon to address issues or undertake activities in everyday life (Schostak and Schostak, 2013). This also effectively describes the field of naturalistic inquiry when applied to the study of human beings in their “natural” habitats undertaking their everyday lives. In the study of human activity, Weber for example argued that “meanings” and human action cannot simply be extracted from a study of so called objective “social facts” that are independent of their value, their connotations for lived experience. Thus, the influential “Chicago school” of symbolic interactionism in sociology drawing on the pragmatism of George Herbert Mead (1934) argued that one cannot know the meaning of an observed action until engaging with others in their ordinary everyday settings (e.g., Whyte, 1943) in order to explore their vocabularies of motives (Mills, 1940).

However, in being, or becoming a member, an ordinary participant in everyday life, how may one “know” that ones perceptions of what is going on and what members say is “true” or “real” is not in some way biased, distorted by the very acts of contributing to the accomplishment of everyday life? In short, is the act of becoming a member compromising the critical capacity of the observer? Of course, it can be argued that it is precisely the prejudices, the values, the meanings and so forth of everyday life that sustain a way of life that is being sought. However, if there are prejudices, this implies a contrast that enables a distinction to be drawn between the prejudiced and the “true”. How can one know the difference? What are the necessary principles and practices that enable such a distinction to be made? In essence, this is that kind of questioning that is behind the phenomenological turn in sociology. The philosophical method of Husserl was not to doubt ones beliefs, values and knowledge about the world but to suspend them - that is, take no position either for or against their “truth”, “existence” or “nature”—in order to “see” what remains after the suspension of what is consciously given that cannot be further “suspended”. For Husserl what could not be suspended was the very act of consciousness itself that is always directed toward an “object”—a structure he referred to as intentionality. This led to an understanding about the essential (that is “invariant”) structure of consciousness that in all possible variations it is always directed toward an “object” in relation to a “subject pole”. This insight would then, it was argued, enable the phenomenologist to describe the invariant structures of conscious acts of perceiving objects and of subjective organization. For example, in observing an object—say a tree—consciousness can be variously directed toward it: from one side of it to another, by getting up close and touching it, by smelling it, by trying to push it. Each act gives a bit more information about the structure of the object. By looking at other objects and following the same procedures one can see what is similar and different and thus identify what are the invariant features—that is, those that remain the same no matter the apparent variation—of a given object. For Husserl this phenomenological method revealed two realms, as it were, of conscious observation: the philosophical and the everyday. This latter he acknowledged was compatible with the descriptions of it by pragmatist perspectives drawing from William James, John Dewey, George Herbert Mead. Alfred Schutz (1976) applied Husserl’s philosophical insights along with those from pragmatism to develop a phenomenological sociology to explore the everyday realm, the paramount reality he called it. For him, the shortcoming of pragmatism was that it did not suspend their everyday attitude of taken for grantedness concerning the “truth” or “reality” of their perceptions. In a sense, as in Debord’s (1994) critique of contemporary society, there is the danger of the taken for granted observation or the spectacle dominating and indeed replacing the real so that what counts as “truth” seems indistinguishable from illusions, make believe or indeed lies—a condition many have called “post-truth”, particularly in reference to the Trump campaigns and presidency and the British campaign to leave the European Union (Schostak and Goodson, 2020).

Broadly, then, the objection is that observations of what is said and done are naive to the extent that the face value of what is being perceived and how it was being interpreted and justified is not subjected to a critical process of suspending belief in the truth, existence, and nature of what is being observed. Of course, everyday life includes objects of consciousness that do not have mathematical like qualities of precision and that cannot be measured as such. Thus, there are objects that are not arbitrary but cannot be fully grasped in their essential—invariant—structures, processes or nature. Tragesser (1977) called these “prehensions”. It is a useful term to apply in social contexts where what happens or what is perceived is not fully grasped but cannot just be “wished away” arbitrarily. To the extent that they are not arbitrary, they are “objective”, that is, independent of the whims and wishes of people that they were otherwise.

In practical terms this “objectivity” can be brought about by what Husserl called eidetic variation, or what sociologists call “triangulation”. Both involve processes of variation, the first through imagination, the second through perception. For example, a mathematician can imagine a triangle, its objectivity is underpinned not by its “natural occurrence” in the physical world but as an object of thought. This object is not arbitrary. Although the length of the sides can be varied to produce different kinds of triangles, it is not possible for example to bend a side, or for an additional side to be added without “breaking” the idea of the triangle and producing something different, say, a rectangle. This process of systematic variation reveals what is invariant, that is, what does not change, or is common to all possible variations as a criterion for a triangle to remain a triangle or a chair to remain a chair. Similarly, on a map, a position can be defined by correlating—or triangulating—its latitude and longitude or its position in a grid. Metaphorically, the validity, objectivity, and, indeed, reliability of an observation, an object, a category, a meaning, a state of affairs, or an event is increasingly established through correlating—or cross-checking—a multiplicity of viewpoints directed toward it over time and across different contexts. Thus in the social world where spectacles can be fabricated to produce a false sense of the real, what looks like a street of houses at first sight, might—on further inspection—turn out to be simply a facade constructed for a film set. By walking up to the facade, trying the doors, walking around the back of it, talking with people working at the site, and so on, its

nature can be assessed. To come to an appropriate judgment with regard to the validity of the street, more than one method and more than one perspective had to be employed. In social settings, naturalistic observers can talk with—or, more formally, interview—a range of people, in order to see whether they share understandings about given phenomena. These understandings can then be compared with what is seen during observations where the phenomena described in the interviews are supposed to occur and contrasted with other kinds of social phenomena. The more agreements there are between different methods and viewpoints on social phenomena, the stronger, it can be argued, the triangulation. Through a process of comparison and contrast distinctions can be made where one might say, “this” is the same as “that” but only has a family resemblance to, or at least apparently looks like some other “that”. In the latter case, there is a critical distinction to be made, a frontier to be maintained, as it were between “this” and “that”. These frontiers may be simply useful category boundaries creating taxonomies that enable people to navigate, manipulate and address attention to a complex dynamically changing world about. However, that analytic “utility” can become charged with values and be emotionally laced when for example distinctions between “good” and “bad”, “safe” and “dangerous”, “us” and “them” are made. This is a process of studying social phenomena that, is grounded in observations and accounts drawn from the experiences, the practices, the discourses of people as they go about their everyday lives. To that extent it is an essential feature of naturalistic observation.

Through our observations grounded in “natural” contexts, can we go beyond descriptions and start to offer analyses that develop theories and show causal relations? Mills (1940) for example explored the motives given by people to explain their actions. Explanations provide reasons for action, for “what is going on”. In that sense, people deploy everyday theorizations of why things happen and how to make things happen. Thus, unlike the mechanical “causes” of effects that laboratory experiments on material substances can identify, human behavior involves “wilful”, “intentional”, “reasoned” forms of behaviors as well as what may be called “unconscious drives” that are socially and culturally framed as distinct from “instincts” that are genetically inbuilt, programmed, that is, biologically driven independently of social learning. Thus in looking for the “causes” of human behavior we can observe and take note of the discourses, the narratives, the anecdotes employed in everyday conversation to justify behavior. Some of these behaviors have a certain regularity about them such as habits, routines, and customs that occur according to context and circumstances or perhaps vary according to different places, times and circumstances. Such regularities provide another source for theorization and prediction concerning the why and how of “what is going on” and what will happen next. Differences may be noticed due to the gender, age, social class, ethnicity or faith of the individuals involved in a given context. Indeed, people put a lot of effort into making life as predictable as possible—whether as bus timetables or the enforceable laws of a given society. Some individuals and classes of individuals may employ both lawful and unlawful power over others to coerce behaviors. The use of this power may be said to be justified according to the “natural laws” and “rights” that have their source in some religious, political, or legal order. However behaviors are justified, the naturalistic observer grounds explanations of them in the everyday life accounts given by the actors being observed. Glaser and Strauss (1967) systematized and popularized this approach as “grounded theory”. However, grounded theory has been criticized for its positivistic practices since it involves “positivistic” or statistical-like reductions of what is common in everyday life to ever more general categories or themes (Charmaz, 2006). In this process the lived particularity of individuals, their existential solitude and uniqueness is lost, repressed, or at least, submerged. Husserl (1970) tried to overcome such positivistic trends in his crisis of European sciences, a book that sought to critique the contemporary mathematization of social and material realities. It is a critique particularly relevant to the digitization of biological and social realities resulting in what Foucault called a bio politics where living systems are increasingly subject to surveillance and control (Zuboff, 2019).

In all this complexity, how does one avoid getting lost?

Orienting

It would be helpful to have a map. Taxonomies offer such a hope. Given the complexity and speed of change in social realities, however, the practice of making taxonomies does not precede but rather is an aspect integral to critical inquiry undertaken in the course of fieldwork. Through continual reflection on the nature of observation as one enters the field, distinctions can continually be made about the ways of seeing and not seeing what is going on “in the wild” or under “natural” rather than controlled situations and contexts. In doing this a first taxonomic strategic decision is made: whether to impose categories theoretically or to seek them as a process of engagement through observation on the ground. It is argued that the latter is the appropriate approach for “naturalistic” studies “in the wild”. Secondly, having discussed what counts as “naturalistic observation” the discussion turns to the role of the researcher: that is, how one positions oneself as researcher in relation to others in “naturally” occurring social settings. A second taxonomic distinction can then be made between observers as “outside” the scene or “inside”. Entering “inside” natural settings means entering as a participant however “neutrally” positioned as a “fly on the wall” researcher. Entering as a researcher then means making decisions that have taxonomic implications for the form of naturalistic observation to be undertaken, about how, even whether, to reveal the nature of the role being adopted. That is to say, naturalistic observation may involve participants being either “covert” or “overt” or at least “sly” in terms of revealing the purpose of their presence. The third step in the discussion involves recognizing the relation between “strangeness” and “familiarity” that is involved in entering social situations, scenes of action and social worlds as a researcher. Indeed, the discussion turns on the question of how to render the world of the familiar, the taken for granted, the “normal”, visible as socially constructed and fragile rather than as a “given” that is “natural”, “solid” and cannot be changed. Rendering the world “visible” is not simply a matter of making descriptions based upon observation, but of inquiring into what is not so easily observed: meanings. A further taxonomic

distinction can thus be made between those studies that seek description of what is observed as an “outsider” and those that go beyond descriptions in order to seek the meaning for participants of what is being observed. This latter involves engagement with the subjects of the research even to the extent of becoming actors who are inducted into the lived realities of those who are the subjects of the research. Thus, there are further taxonomic implications to be drawn between forms of naturalistic observation that either accept the descriptive givens of what is being observed without seeking to engage in action and those that seek to use the findings as evidence to support change and development as in forms of action research and evaluation. Any taxonomy detailing alternative approaches suggests there are choices to be made in the field. Each such choice has implications for the nature of the research methodology and methods employed, the data to be collected and the theoretical work that results. The approach to naturalistic observation adopted can either be sensitive and responsive to the particularities of the situations, circumstances and contexts faced or be imposed rather like a methodological straight jacket. The first, it is argued here, is appropriate to social research “in the wild”, whereas the latter is more appropriate where all variables are under control, as in laboratory experimentation. Each may reveal “what is really going on” in their different ways and for different purposes. But as we move out of laboratory-like settings, what is really going on becomes more difficult to notice. Each step further into the “wild” involves thinking critically and clearly about the kind of approach to naturalistic observation being adopted. It is not just a matter of selecting from a taxonomy of different approaches and “tools” of naturalistic observation but of critically assessing each step in the process of finding out “what is going on”. With each step into the wild, new relations with others are formed that require a critical re-assessment of one’s own position as “researcher”.

How, then does one critically position oneself as a naturalistic observer, in the wild, in an everyday setting?

Participant observation

Within the context of naturalistic forms of observation, participant observation provides a way of thinking about how to position oneself in the lives of others. Evolving from the writings of adventurers and missionaries and, later, the early anthropologists, it was adopted by sociologists who wanted to explore the meanings and experiences of people rather than measuring and counting (deWalt and deWalt, 2002). At present, participant observation is employed in any research, methodological perspective, or discipline in order to gain insight into the lives of others. In many ways, it is more than a method for the production of knowledge, understanding, and theory. It is a way of life which—for some—may last a lifetime. Yet, the very act of “naturalistic” observation is a conscious artifact as it were that disturbs the acts of observation of the observer. It is not normal to say “yes, I am a naturalistic observer, please take no notice of me and go about your business so that I can observe what it is”. To what extent then is concealment or deception necessary, echoing metaphorically, a camouflaged hut used by wildlife observers?

While we do not live in laboratory settings, we do live in settings that are variously manipulated whether by ourselves or by others. What is important in this for “naturalistic observation” is both the seeing and the not seeing. How to see like another in a given “naturalistic” situation, is also what not to see. It is also about how the others being observed “see” and also “not see” the naturalistic observer. How one engages as a participant then, that enables these strategic analytic distinctions is critical to the formation of analyses and theories while grounded in the life world of particular members. In some way, the members have to see the observer as someone who fits the natural setting otherwise the setting will be disturbed and the observations thereby compromised. Moreover, the observer has to see “more” than any of the individual members, otherwise connections between different contexts, circumstances and actors essential to building theory, particularly critical theory will be overlooked.

According to Spradley (1980: 58–62), there are different degrees of participation—complete, active, moderate, passive, and nonparticipation. As a passive participant, the observer is present but not engaged—more a bystander looking at a scene of action rather than being part of it. Rather than merely hanging around, loitering, or being a bystander, one can then try to act like the members by moving on from the stage of recording what went on to actually joining in—but not enough to be acceptable as a member. Going further than this involves entering the world of the other as an accepted member—like Whyte (1943) when he joined Doc’s gang in Cornerville. However, to be a complete participant observer, Doc would already have had to be a gang member who decided to undertake research while participating. The parallel would be, say, a teacher who decides to research the classroom—perhaps, focusing on their own practice in order to improve it as in Action Research.

In each case, participant observation involves being with others—whether living with people far from home whose language, customs, or behaviors are not known, as did Malinowski in his study of the Trobriand Islanders, or, perhaps, like Whyte (1943), where the participant observer goes to live a slum area, or join a criminal gang (Patrick, 1973) or study power elites (Mills, 2000). In these cases, there is a clear demarcation line between my home and their home, my way of life and their way of life, and where I go to visit strangers with the object of becoming familiar with their way of life, their view of the world. The demarcation becomes less obvious when what is observed is already a part of the researcher’s everyday life as, for example, in observing what happens in one’s life, one’s own community—say in a school or in one’s own place of work (as in action research) and the virtual worlds of globalized communications technologies. Whenever, wherever, and however people interact, share experiences, and, in some way, organize their lives in relation to each other, it becomes a possible focus for the participant observer. Understanding the nature and process of being a participant observer begins only at the moment of joining.

Joining

To know the world of others—to understand a particular group—involves joining them in some way, being with people in their everyday locations and activities, and learning how to do what they do in the ways that they do it, in the locations where they do it. Joining with, witnessing what happens, and acting alongside others makes participant observation more than just a method or technique for data collection. The participant observer is part of the data itself—that is, responsible for how this data is to be represented, analyzed, interpreted, and used, as in this example from a narrative account of fieldwork by [Schostak \(1980\)](#):

Fig. 1 An intentional network.

Entering the tutor room, a chemistry laboratory, under the gaze of Jacko's mates, I feel inverted—watched, examined. Where shall I sit?

Carol, a girl I know, smiles, invites me to Jacko's group.

The tutor, a teacher I know well enters. He ignores me.

"Jacko. All of you, come and sit at the front."

No one moves. I feel uneasy.

"Come on now!"

"But there's gas taps at that table."

"I don't care, I've told you to sit down here. Now do it."

Carol moves, the rest follow and I am last.

After the formalities of the tutor period—registration, reading a pupil news letter—the teacher approaches smiling. "So you're following Crawley around today?"

"Yes," I turn away as best I can.

"Good luck," the teacher retreats to the doorway where for the remaining time he blocks the escape of three girls who push against him.

Being there and living it, the researcher is a direct participant. It is an approach owing much to the sociologists who, during the first-half of the twentieth century, became known as the Chicago School. Their attention was on the city as a natural laboratory of human behavior ([Park and Burgess, 1925](#)). For example, Thomas studied the communities of Polish immigrants (1918)—and, Whyte, the Italian community (1943)—as the natural areas produced by human habitation and use. In any city, there are many such areas, such as the business district, the Red Light area, or the territories of particular gangs, as well as the secluded areas of the wealthy. In each case, the initial concern is to gain entrance. This, typically, involves finding a gatekeeper—that is, someone whose knowledge and authority can ease the passage into the world of others by hanging around sufficient times in a place where the target group tends to meet until someone begins a conversation. Such gatekeepers are easier to identify and contact in formal organizations—for example, the headteacher or principal of a school, the leader of a youth group or sports team, the head of a committee or director of a business. In other circumstances, greater secrecy may be vital as in the study of a criminal gang. To openly identify oneself might cost one's life, or, at least, physical health. Whether open or covert, participant observation requires developing strategies for meeting, joining, and engaging with others in their everyday scenes of action.

Ethics, *dramatis personae*, locations, and scenes of action

Joining with others means getting to know the members of scenes of action—the *dramatis personae*—getting to know their values, their reasons for action, and their ways of acting. For example, being with Jacko meant going where he went, meeting other people along the way—pupils and teachers—and, when engaging with these others, reflecting ethically on the decisions concerning what to say, how to act, and what and how to record. Observing Jacko's (A) actions toward his mates (C, D, and E) and say a teacher (B) as they approach or keep their distance, patterns can be observed and noted (Fig. 1):

Each individual acts in some way toward another—whether in friendship, hostility, or authority. In phenomenology, this directness toward another is called an intentional relation. The diagram, thus, describes an intentional network (Schostak, 2002) of people as they repeatedly engage with each other. In Fig. 1, Jacko's (A) attention is directed, in various ways, toward B, C, D, and E. B also has a particular relationship of mediation with G (say, a senior teacher, a parent, or a police officer, or a rival gang leader). This mediation may play out in events such as B telling G about A or misleading G about A's real intentions. Or, instead of people, the focus could be upon valued object B that A and G both desire hence leading to a conflict of interest and thus contributing to a study of the ways in which such conflicts are handled. The participant observer becomes a part of this structure, say G, as participants recognize and trust the researcher and as a valid part of the scene able to apply the ethics of the participants—that is, what is right, good, fair in their eyes.

Following Jacko throughout a particular day was part of a larger study of a school and its community (Schostak, 1983). The ethical principles for the conduct of the project had to be agreed. To do this, the participants needed to have an idea of the purposes of the project, what it involved and how data was going to be used. They needed to be assured that they could not be identified and that what they said and did would be treated confidentially so that others could not use the information to harm them. Such principles can be seen more formally in the guidelines provided by discipline-based organizations such as the American Educational Research Association or the British Sociological Association. Indeed, particular organizations—such as hospitals and universities—typically, have their own ethics committees that oversee research involving their institutions. In practice—for each organization—ethical protocols need to be tailored for the specific circumstances of projects. With a formal organization such as a school, general principles may be agreed in writing with its governing committee. Letters describing the research and assuring confidentiality and the anonymity of names in the use of data will be sent to parents as a basis for agreement to be involved in the research. Participants may be asked to sign letters that confirm their understanding of and agreement to the conditions of participation. However, ethical practice is not simply reducible to—nor does it stop with—satisfying the formal ethical procedures of committees.

The different circumstances of each meeting continually pose ethical issues. Not all of the people—the *dramatis personae*—involved in a given scene of action in the various locations of the project may be aware of the status of the participant observer as researcher rather than as an ordinary member of the scene. Indeed, Hilbert (1980) argues that there is always a degree of covertness in research, as aspects of the researcher's biography and later uses of the data remain obscure in the eyes of participants—whether through lack of understanding, familiarity with academic discourse, or disinterest. In the extreme circumstance of joining a gang, or being a football hooligan, it may be argued that not only may acts be seen that are criminal, but also, to gain trust as a bona fide member, illegal acts may have to be committed requiring a rethinking of what it means to act ethically (Ferdinand et al., 2007). Without trust, no access to the world of the members would be granted, thus no research into their life-world is possible.

The researcher needs to demonstrate a commitment to the reality of those being observed, however they define this reality as being true, natural, or right—it is what Quine (1948/1949) would call an ontological commitment. Commitment to what there is in the world is revealed through people's vocabulary, ways of talking, ways of justifying beliefs and actions, as well as in carrying out the kinds of acts expected of members.

In this way, a shared sense of reality is constructed that acts as the natural, taken-for-granted, familiar basis for undertaking social action. Typically, when this familiar world of shared ontological commitments is disturbed, its constructed features are revealed.

The familiar and the strange

Schutz (1964) described how being a stranger sensitizes the researcher to practices, knowledge, beliefs, and values that participants take for granted as being true, real, or right. In learning how to belong—to be a part of a scene of action—a distinction between two worlds is posed: that of the stranger and that of the members of a given group or society that the stranger attempts to enter. Participant observers, similar to strangers, can take nothing for granted—a standpoint paralleling the phenomenological attitude of suspending any position for or against the truth and reality of the world. Presupposed by this phenomenological attitude is a domain of taken-for-grantedness—or paramount reality that is placed in suspension and becomes the focus for the sociological phenomenology of Schutz. As with the symbolic interactionism (Mead, 1934; Blumer, 1969) of the Chicago School, to understand the everyday worlds of people and learn the meanings that actors gave to actions, objects, and the scenes of action in their everyday lives, participant observation was a natural strategy. For symbolic interactionists, it is not enough simply to observe behavior. Behavior has a symbolic dimension. Its meaning to an actor and its relevance to a social situation cannot be known without asking the actor(s) involved. The focus of the symbolic interactionist, then, is upon the symbolic nature of the actions and interactions of people who engage with each other in social settings. Mead (1934) is considered the father of symbolic interactionism, although the name was coined by Blumer (1969). Being a participant observer, however covertly, heightens awareness of the artificiality or socially constructed nature of the ways in which people behave in everyday life. Whether standing in bus queues, waiting at hotel

reception desks, or relaxing at home—what are the regular behaviors that occur? Why do they occur in that way? Could they be changed as in changing the rules of chess? Garfinkel (1967) demonstrated the fragile nature of social rules in his experiments where, for example, a student might go home and act like a stranger, thus transgressing the tacit rules of normal behavior—often, leading to angry reactions by family members. Less dramatically, when participating in Jacko's activities during the school day, the researcher—as a 32-year old—could not pass as a 14-year-old pupil. What becomes noticeable then, are the moves of inclusion as well as those of exclusion made by different members of the *dramatis personae* in the classroom, in the corridors, and out in the playground. Although Jacko had given permission to be followed, he always placed a distance between himself, his friends, and the researcher, although others invited the researcher to join them. Through such a process of seeking permissions, invitations to join, or distancing and excluding, social space becomes dynamically organized as boundaries between who is in, who is out, who is close, and who is distant. This negotiation of boundaries also took place between the researcher and the teachers and the placing of boundaries varied according to circumstances. Thus, the physical reality of streets, houses, and parks are continually mapped and remapped by the ways in which individuals project and negotiate boundaries around them over time. To see it requires distinguishing between “the scene of action, the human picture of that scene, and the human response to that picture working itself out upon the scene of action. It is like a play suggested to the actors by their own experience, in which the plot is transacted in the real lives of the actors, and not merely in their stage parts” (Lippmann, 1922). In this early statement can be seen the seeds of studying social action like a performance on a stage where the analysis of performance, talk and narrative structure, and a focus on biography becomes important rather than static descriptions of states of affairs (Goffman, 1959; Schostak, 2006).

The projection of a world and its boundaries is most obvious when there is a sense of disjunction or clash between alternative perceptions. This can be seen in the following transcript extract from an action research project involving creative practitioners (artists of various kinds), teachers, and pupils (funded by CapeUK Creative Partnerships for Education (CAPE) 2004–05; see also Schostak and Schostak (2008: 48–50)). The focus was on making representations of local communities—both real and imagined. The pupils—aged about 10 years—had just watched a video that had been made of their area:

Boy: ... if you looked at the surroundings they were like, you know “oh I wouldn't like to live there”. Cos if you looked at all the houses they were all boarded up and, all the graffiti and smashed bottles (...)

JFS: So would you have done a different story, you know for (place name)?

Boy: yeah.

JFS: What would you have shown?

Boy: Well I'd have shown the good bits, like the park and ... (laugh) hmmm, there's a point.

Girl: The good parks, the local parks are all trashed up so we don't get anywhere to play.

Immediately there is a clash between the picture in the head and the picture on the video. There are also the explicit and implicit viewpoints of the *dramatis personae*: the boy, the girl, the creative practitioners, the teachers, and the unnamed people who trashed the parks. The participant observer can elaborate the multiple pictures in the head by meeting, observing, and talking to representations of the different viewpoints. How these viewpoints relate to each other can be represented as intentional networks in Fig. 2 where the children are represented by group C who are able—through their reflection on their community—to imagine alternative visions of community that are, perhaps, seen to be enjoyed by group B. The depressing reality experienced by group C is represented by the trashed parks. However, group B never enter the children's location. For them, it is—for all practical purposes—invisible.

Fig. 2 Mirror groups (Schostak and Schostak, 2008: 172).

The central bar symbolizes a boundary dividing the two groups—B and C—and thus two ways of projecting a picture of the world. By participating in each group, the researcher A is able to build up pictures (a1, a2) of how each constructs their ways of seeing the world with their different ontological commitments: whether the hard-and-fast realities of the social organization of gang territories or the views and fears of locals residents who want to freely walk the streets, or the police and other figures of social and political authority who have quite different conception of how the world should be organized. If group B represents the dominant voice in the social, political, and economic organization of society, it will see itself as exemplars of good order. The boundary that delimits their picture of the world acts like a mirror reflecting back their own values (represented by the double arrow in the diagram). For B, C is rendered marginal at best—perhaps an underclass—invisible at worst. The “bar” can be explored as an infrastructure in itself, representing, say, communications technologies both to connect and to separate users into exploitable on-line communities (Zuboff, 2019).

Rendering the invisible visible means transgressing, perhaps deconstructing, the bar between the dominant and the powerless. The role of the participant observer is already transgressive. Between these multiple camps, the participant observers are always, to a degree, out of place because they are always between worlds. The danger is in slipping into a position of authority granted by some superior insight into what are the right ways of seeing and of telling the truth.

Fieldwork as a basis for validity, generalization, reliability, and objectivity

Fieldwork involves making records of what is seen, heard, and done in particular locations under particular conditions: making extensive notes, maps, and drawings; committing to memory what happened; recording sounds and images; collecting artifacts and documents, etc. It involves decisions regarding how obvious the process of recording will be. Note taking when being a member of a gang is unlikely to be perceived as natural but, as a student in a classroom (Hilbert, 1980), it is perfectly natural. Thus, depending upon circumstances, making notes may take place either during or following the scenes of action.

Even as a bystander, or recipient of stories, the participant observer becomes a member of the *dramatis personae* of a scene of action and thus as a member of the different *dramatis personae* that engage with each other in scenes of action across a range of locations and becomes a carrier of the local stories similar to the other members—each with their views. The multiplicity of views constructing stories of what happened, with whom, how, where, and why are retold for particular purposes and become vital elements in the sense of reality and drama of everyday life.

Each story retold connects to other stories, weaving each actor, the scenes of action, and the objects involved in the action into a reality, a sense of my place, my people, and my world where what happens becomes familiar, expected, routine, and ritualized and where the unusual stands out. Aspects of one story may recall other stories—stories that elaborate on the character of one of the actors, or add to a sense of pride, frustration, or tragedy whether it is “teachers always pick on you like that” or “that’s what always happens to people like us.” This connectedness—or intertextuality—composed of shared and sharable anecdotes, local histories, and biographies becomes the vital data of the participant observer (Schostak, 2006) who also contributes to the stories through various degrees of participation. This intertextuality, with its multiplicity of viewpoints scanning shared or disputed locations, territories, scenes of action, and events, contributes an intersubjective sense of generalizability, validity, reliability, and objectivity of observations and accounts described during fieldwork. More specifically—in phenomenological terms—across all the variations of viewpoint some relatively invariant or typical relations, actions, objects, and meanings attributed to them can be identified, thus leading to judgments as to the generalization of the observations and analyses made. The process is, typically, referred to as triangulation. Features seen with one group and in one scene of action can be compared and contrasted with other groups, scenes of action, and locations. With the aim of identifying the range and limits of variation across individuals, forms of social organization, and locations, the participant observer can seek out comparative and contrastive situations, people, and locations in order to test out emergent understandings, analyses, and theories in a process called theoretical sampling.

The participant observer, then, is continually learning, making analyses, and searching for opportunities to test out emergent understandings and theories concerning the social world being studied. As well as making field-notes to describe observations of people, events, and places, analytic memos can be written in order to formulate potential categories by which insiders describe the circumstances of a situation and provide motives for their action (cf. Mills, 1940) and theoretical memos on emergent theory that can be tested out through further observations (Schostak, 2002). The participant observer is interested not just in a single subject’s point of view but in how the sense of a common world, shared reality, and orchestrated behavior is brought about as an intersubjective reality in the lives of people.

When the researcher is able to represent the intersubjectively constructed world(s) of actors in ways that they recognize as their world, their definitions, and their way of doing things—whether through performance as a member or in spoken and written accounts—this achieves a degree of validation and reliability. More critically, participant observation by seeking out the multiple voices and perspectives and learning from their viewpoints provides a critical resource for researchers in their debates with regard to what counts as knowledge and its “truth”. Whether it is the view that there is the inevitability of a distortion—a violence even—in the interpretations of the researcher as shown by the critiques of feminists or by critical race theory or poststructuralism, the debate is continually renewed, shifted, and challenged by a return to the field.

Truth out of place

There is a sense of “ordinariness”, of the “routine”, the “predictability” underlying the idea of everyday life. However, this “everydayness” can be “naturally” interrupted, suspended, put out of joint by personal, local, regional, national, world crises. Where [Garfinkel \(1967\)](#) developed the phenomenological method of “suspending” or “bracketing” in his fieldwork practice as a method of causing trouble in order to lay bare the otherwise taken for granted social structures and practices that gave constancy to everyday life, such suspension can be bought about by accidents, natural disasters, economic crises, civil strife, technological revolutions, wars and epidemics that jolt or even render the “everyday” of yesterday as no longer valid, re-achievable.

Moreover, what such crises may make visible, are not only the lost familiarity of the everyday but the fundamental disagreements, injustices and indeed violence that have been covered over by its veneers. In these contexts, naturalistic observation addresses the struggles of people to make sense of their altered situation, to “return” to what was, or to call for a better world to be built from the ruins. In doing so, naturalistic observation can make clearer what matters to people in their lives, what is at stake in adopting one view or course of action than another. Indeed, it may well seem and be argued by many that the “truths” that had been established as a natural part of the social, economic, political, cultural order of life are “out of place” or no longer relevant for the emergent or desired realities of members.

The Covid 19 pandemic that led to the suspension of much of the world’s economic and social life in 2020 was just such an event. The “normal” practices of social contact and greeting were suspended by demands for “social distancing”. No more hugs, handshakes, kisses as rituals of greeting. Breath and surfaces—and the skin is such a surface—became potentially dangerous as conveyors of disease. Where the rich had access to large private secure spaces, for poor families their cramped spaces contributed to insecurity, anxiety, and increases in domestic violence. Masks, disinfectant and measures to avoid close contact when moving around public spaces and inside shops became a “new normal”. Suddenly, overlooked economic activities such as delivery drivers, transport workers, postal services, cashiers, farm laborers, refuse collectors were seen as indispensable in keeping society functioning. Nurses and medical staff were publicly applauded. These were called the front line workers, who largely work in what economists call foundational infrastructures (health, welfare, education, utilities such as gas, electricity, water, sewerage and indeed, banking as a system enabling market exchange) rather than those more superficial less vital economic activities where speculators make money, entertainers seek fame, and entrepreneurs sell their wares. These latter activities depend upon the existence of the foundational infrastructures ([Bowman et al., 2014](#); [FEC, 2018](#)). The Covid 19 crisis had rendered visible the “truth” of the different kinds of activity. Moreover, it occurred alongside a rise in right wing political popularism that offered nationalism as a solution to many complex historical inequalities and injustices as well as alongside an increasing awareness particularly among the young of impending environmental and climate crises. For the naturalistic observer of social life, the degrees of public recognition of the conjuncture of multiple crises creates opportunities for obtaining insights into the subjective and social lives of individuals as they try to make sense of their struggles under such circumstances.

Crisis has a particular significance in contemporary capitalism—it is, as [Friedman \(1962\)](#) argued, the occasion to capture political, social and economic power by having, as he put it, the only ideas “lying around” that provide a solution to the crisis. And capitalism, as many have pointed out, thrives on reinventing itself through crisis (e.g., [Harvey, 2010](#)). However, such ideas are always in contest with alternative ways of producing the “good society” and creating for “ordinary” people a sense of security or at least a hope for a better future. Indeed, it is this feature of everyday life where the “truth” or “facticity” of a given practice, or set of circumstances, can be publicly contested through debate from multiple view points that the early leaders of the French and American revolution saw as a way of embedding and guarding democratic forms of public life. The public, they argued, had eyes and ears everywhere and thus through debate could form opinions and knowledge with a validity, accuracy, objectivity and generalizability that no single person, or indeed, small group could do alone ([Rosanvallon, 2013](#); [Schostak et al., 2020](#); [Schostak and Goodson, 2020](#)). It is in this spirit that [Lippmann \(1939\)](#) argued for the necessity of the oppositional views in the development of “true” public knowledge and [Dewey \(1927\)](#) saw as necessary to the development of a democratic public. In this sense then, the practice of naturalistic observation through research is itself a constituent of and contributor to the more general practice of the development of an informed and informing public. Participant observation thus becomes part of the struggle both to inform and to create a public capable of determining “what is going on” in their everyday lives as a basis for their decision making in everyday life ([Schostak and Goodson, 2020](#); [Schostak et al., 2020](#)).

The significance of naturalistic observation

In summary, as Thomas (in [Thomas and Thomas, 1928](#): 571–572) put it: “If men define situations as real they are real in their consequences.” The task is to learn how situations are defined as a member, how reality is constructed as a member, what it means to be a member, or even to pass as a member of a particular group. This is not to say that the social realities of members are homogeneous. Indeed, where there are disputes or disagreements, these are managed or resolved according to the rules, rituals, habits, beliefs, values, and social positions of the members. For that reason—from an ethical and democratic standpoint—the naturalistic observer records the range of disagreements as well as agreements in order to produce a record that the French political philosopher Jacques Rancière calls being faithful to the disagreements (cf., [Schostak and Schostak, 2008, 2013](#)). This includes not only a representation of the world of those being studied but also extends to the public debates concerning what counts as knowledge and whose knowledge and perspectives are to be included in public debates that affect people’s lives. Naturalistic observation can be the basis for forming “ground up” research designs for descriptive case studies whether of particular forms of social organization

or of wider more complex communities. As a fieldwork method it can be employed in other more deliberately interventionist forms of research, such as action research that has the explicit aim of making changes, or in evaluations that explore the impacts of policy on practice. In each case, naturalistic observation seeks the experiences of people, exploring how through their activities, their discourses, their narratives they construct, interpret and validate their everyday lives with each other. By explicitly drawing upon multiple points of observation, the naturalistic observer can explore the constitutive practices of social life in order to reveal the ways in which material, social and symbolic objects are perceived and given significance in the lives of people. In this way, naturalistic observation can be publicly extended as a tool for the formation of the public so that potentially everyone has access and is a contributor to their own and public understanding about what counts as knowledge, justice, and the good society.

The only way of learning naturalistic observation is to do it, be there, and live it.

Introduction

A primary role of qualitative research is to uncover the unspoken meanings of symbols and ideas held by communities or individuals, to elaborate the beliefs that guide the actions of people, and to document how communities and the individuals within them construct a consensus understanding of their shared world. Historically, qualitative researchers told the stories of individuals who did not hold the power or position to tell their own stories. More recently, critical researchers have shifted their work to give voice to marginalized and oppressed groups—silenced populations. Critical researchers break down the barriers silenced populations face as they seek to gain agency in their own stories (Clifford and Marcus, 1986; Fine, 1994; Shah, 2015).

Although children are frequent subjects of research, “much of the research on childhood has been conducted by adults observing children or by adults reflecting on childhood—both on their own childhoods and on the childhoods of today” (Dell, 2011, p. 5). Adult voices become the expert voices; adult interpretations replace children’s meanings; and adult reasoning gains consensus as the motivation behind children’s action. In this way, children’s voices are suppressed and children’s experiences are marginalized to a subculture of adult experience. In the same way critical theory pushed researchers to take a critical stance that empowers disenfranchised groups, children need their agency as active participants in studies of their lived experiences.

Participatory Action Research (PAR) is one mechanism available to close the gap between subject and researcher (Abma and Schrijver, 2020; Groundwater-Smith et al., 2015). PAR is an inclusive research methodology that requires children be involved in all stages of the process. It goes beyond simply asking about their ideas regarding a topic as part of data gathering or if the presentation of their ideas in the analysis sounds good, PAR puts children in charge of the research, allowing them to be the active agents of the exploration of their lived experiences (Abma and Schrijver, 2020). Photovoice is a particular form of PAR that combines the power of photography to capture, assess, and communicate a sophisticated view of community concerns and ideals that words

alone are difficult to express (Wang and Redwood-Jones, 2001). Carolyn Wang, Mary Ann Burris and their research colleagues developed and shared photovoice as a participatory research method in the late 1990s. They emphasized the importance of the collaborative processes of sharing pictures and the story of the individual's relationship to the image and the environment from which the picture arose.

In the last 20 years, photovoice's use with youth and children has increased. Photovoice with children serves the dual purposes of building on children's methodological skills and developing new pedagogical tools. The use of images and storytelling as a research method, builds on experiences even young children are familiar and engage in their daily lives through play, drawing, and reading with others. Pedagogically, photovoice may provide a new experience intentionally developing the children's voice, social action, and advocacy experience (McKenna et al., 2017).

The majority of photovoice studies with children and youth fall into one of three broad topic categories: health, poverty, and learning and schooling. However, many studies sit in the intersection of these categories. In 2006, Caroline Wang reviewed ten youth photovoice studies focused on public health issues facing youth, the majority of which addressed health issues in low-income urban environments, promoting critical dialog with the youth participants and policy makers. Shah's (2015) study encompassed poverty and schooling in her work with school age girls in India and the impact of traditional roles of women on the potential for empowerment through education. Other studies focus on inclusive schooling. Mackenzie and Talbott (2018) worked with elementary aged children parented by LGBTQ parents to create a more inclusive school environment. Multiple school learning examples include understanding the abilities of students with disabilities (Meyer and Kroeger, 2005; Agarwal et al., 2015), literacy struggles (Pollock, 2019) and disciplinary learning (Cook, 2015).

These works involving children and youth engaged in photovoice, demonstrate its potential to break the lock on adults interpreting children's experiences and give children back their voice. In this chapter, we focus on conducting photovoice with young children and urban youth, and its use to capture how the children and youth understand and value their experiences with nature. The importance of youth developing robust and positive views of nature must not be diminished. Educators and environmentalists are concerned that children are losing connection with nature, an impact that changes the children's physical and cognitive development and their adult environmental attitudes and behaviors (Dell, 2018). As we rush toward a worldwide climate crisis, we cannot afford any generations losing nature experiences that empower them to advocate for the environment and environmental change.

In the remainder of this chapter, we overview the history of photovoice and define it as a specialized form of PAR, separate from photo-documentary work. We then outline the photovoice method as described by Wang and Burris aligned to a condensed method we used for our work with children. This is followed by two exemplary photovoice studies with children. The first study was completed with pre-school age children (ages 3–6). This example highlights modifications to the photovoice methods for use with very young children and introduces what was learned when the children became co-researchers at their nature-based preschool. The second study was completed as part of an urban environmental club. The co-researcher youth in this study were middle school age children (ages 12–14) in an urban public school. Unlike the preschoolers in the first example, the youth in the second example had limited nature experiences, but we learn how their experiences in nature reflect their position in the community. Finally, we conclude with a discussion of the importance of photovoice to engage children as co-researchers of their world and experiences providing them with the agency to teach adults and advocate for a sustainable future.

The history of photovoice

Photovoice builds on Freire's (1970) critical examination of participants' local communities to derive educational opportunities through line drawings leading to text-based problem-posing education. In 1989, Rhoda Linton turned a feminist lens on Freire's problem-posing to focus specifically on issues facing women. Linton (1989) acknowledged women share knowledge and experience through a range of representations beyond text including, storytelling, cooking, arts, crafts, and political action. Each representation provides detail and texture to the lived experiences of women. Linton believed when women engaged in cooperative group activities, they began to understand their collective oppression within the status quo and identify public policies and actions leading to liberation. A characteristic of feminist research methods for Linton is the need for strategies that are open, inclusive, accessible, and creative in order to meet the varied educational backgrounds and lived experiences of women across the world; photovoice provides this research avenue.

Wang and Burris's (1997) article *Photovoice: Concept, Methodology, and Use for Participatory Needs Assessment* introduced photovoice as a research method. The methods arose from their work with women in rural China. They used photographic images first to address critiques of Freire's use of drawings by men as part of his cultural circles (Maguire, 1987), and second because the photographic images added simplicity to data gathering. "Because virtually anyone can learn to use a camera" (Wang and Burris, 1997, p. 370). As a research tool, a camera has many advantages. Participant researchers with cameras have access to settings and locations that external researchers may not readily gain access to or initially deem worthy of study. Wang and Burris found their photovoice participants took pictures of events and locations that were not typically accessible to or considered research settings, but were

integral aspects of the women's lives. An additional strength of photovoice they discuss is its adaptability—to the purpose of the research, the needs of the participants, the community setting, or issue under studied.

Photovoice as participatory action research

Photovoice is particularly relevant to Participatory Action Research (PAR). Similar to [Stringer's \(2022\)](#) community-based participatory action research (chapter 19 in this volume) the critical participatory goals are the same but in the case of photovoice, the photographic images create a powerful level of ownership for research participants. The use of a visual image empowers the participants to initiate the story, its meaning and centrality to their lived experience. With photovoice, the images engage the participants in the process of identifying and representing their experiences similar to Freirean problem posing's use of line drawings ([Meyer and Kroeger, 2005](#)). The shared images and stories honor the expertise of the individuals as actors in their own experiences and engage participants' in the development of and participation in democratic decision-making and public policy.

Photovoice is not about creating a beautiful photographic image, nor is it photo-documentary work. [Sontag \(1977\)](#) described image photography as a relationship between the photographer and their context and purpose for taking a picture. It is the viewer's role to form a relationship of their own with the photograph based on what the photographer has provided. In this way, a "photograph, like a riddle or problem to be solved, must be decoded" ([Meyer and Kroeger, 2005](#), p. 188). In photo-documentary work, the photographer is interpreting their subject's reality; selecting images and representations through the photographer's lens; creating the reality important to the photographer's narrative. The loudest voice in photo-documentary research is the voice of the researcher. In photovoice, the participant researcher fully owns this narrative. Their voices are activated by identifying what to photograph and selecting the photographs that represent their reality.

The photovoice process

In its early use, the photovoice process was defined as a nine-step strategy deeply embedded in community action and policy development ([Wang, 2006](#)). However, as it has expanded beyond its origins in health policy and, as technology has changed how we take pictures, some steps have become less prominent. [Table 1](#) shows Wang's original nine stage methods aligned with a condensed, four stage method ([Meyer and Kroeger, 2005](#)). A strength of photovoice is its adaptability based on the needs of the community of researchers, we found this consolidation of Wang's original stages ensured essential aspects were retained but other steps that might have been too difficult for young children or unnecessary with current technology were not included just to meet a methodological requirement.

Establishing the research framework

The activities of this first stage happen before any pictures are taking. Its purpose is to develop a cohesive research community who are aware of not only the purpose of the research, but their roles and responsibilities, its potential for growth, and its potential for conflict. [Wang \(2006\)](#) articulated four inter-related activities in this framing stage. Although some of these activities are technical, use of cameras or image storage, most of the activities involve honest discussions with the participants. Unlike more traditional research methods, rather than identifying research questions, in this stage the photovoice researchers discuss their lives and experiences to identify an appropriate audience that needs to learn from their life experiences. The identification of the audience for their research becomes a guiding idea in the next stage.

Table 1 Consolidated photovoice stages ([Meyer and Kroeger, 2005](#)) aligned to ([Wang, 2006](#)) stages.

<i>Photovoice stages (Wang, 2006)</i>	<i>Consolidated stages (Meyer and Kroeger, 2005)</i>
1. Select and recruit a target audience of policy makers or community leaders	Establishing a research framework
2. Recruit a group of photovoice participants	
3. Introduce the photovoice methodology to participants and facilitate a group discussion about cameras, power, and ethics	
4. Obtain informed consent	Taking pictures
5. Pose initial theme/s for taking photos	
6. Distribute cameras to participants and review how to use the camera	
7. Provide time for participants to take pictures	Image selection and theme generation
8. Meet to discuss photographs and identify themes	
9. Plan with participants a format to share photographs and stories with policy makers or community leaders	
	Presentation

Because the goal of photovoice research is to give voice to an oppressed group, the research participants need to be informed about political or policy issues their research may confront. Everyone needs to know how to act safely in a potentially charged environment. Additionally, Photovoice participants need to understand and discuss issues of power and ethics when taking pictures of other people or particular situations. During these framing activities Wang and Redwood-Jones (2001) suggest clear discussions about questions such as: how do you approach someone to take their picture; can you take pictures of people without their knowledge; or when is not safe to take a picture?; must be addressed. Finally, Wang and Redwood-Jones (2001) explicitly include discussion of informed consent. Photovoice researchers need to understand they are researchers and research participants who are consenting to being part of a research study that may cause upset the status quo.

Taking pictures

Once all the photovoice participants understand their role in the research process, the research transitions into the taking pictures stage. This stage includes deep discussions about the research theme and brainstorming ideas of images that might represent these themes, so once they begin to take pictures they are clear about the focus theme. This generation of a research theme and how the theme might be represented with images from the researchers lived experiences' substitutes for a formally articulated research question. After the research theme is understood, the cameras are distributed and basic photography skills practiced. The type of camera is an important consideration as ease of use needs to be balanced with safety, image security, and cost of printing. In the digital age, camera skills may focus more on centering objects, direction of lighting, or safe image storage than on the technical skills of winding on or loading film from when film-based cameras used. However, depending on the age and experience of the research participants, picture-taking practice may be required. Once this preparation is complete, a picture taking timeframe is agreed upon and the photovoice researchers begin documenting their experiences.

Image selection and theme generation

As a form of action research, this photovoice stage is likely to occur in iterative cycles in conjunction with the refining and revising of the research theme generated in stage two. This stage includes multiple cycles of "selecting photographs, contextualizing or storytelling and codifying issues, themes or theories—occurring in group discussion" (Wang, 2006, p. 151). When selecting photographs each participant picks a few of their images to share with the group. The contextualization of the selected image is guided by a series of questions termed as Wang termed as SHOWeD (Wang, 2006, p. 151).

- What do we See here?
- What's really Happening here?
- How does this relate to Our lives?
- Why does this situation, concern, or asset exist?
- What can we Do about it?

Each participant uses this five-question sequence as they share their images and their relationship to the research theme. The group listens for common ideas and themes arising from the collection of pictures from the group. These themes may lead to a new photo-taking round or the group may determine it is time to move to the final stage.

Presentation

This stage reconnects with stage one as the research participants prepare their findings to present to the audience selected in stage one. Participants determine the most impactful format for presenting their finding, as well as when and where the presentation should take place. Depending on the age of the researchers, subject matter, and audience, the presentations might include displays in a library or other public space, presentation to a parent group, a council meeting, or a formal research paper presentation at a public conference.

Although photovoice is adaptable, it is not ill defined or unstructured. Some processes and steps can be consolidated as we have done or some may need greater emphasis to meet the needs of the research participants, but each stage is important. If a research facilitator does not prepare new photovoice researchers with all information detailed in the steps, they are diminishing the photovoice researchers' role as expert arbitrators of their experiences. Photovoice research, "provides a compelling, critically reflective experience wherein students think and rethink their engagements with self and other" (Latz et al., 2015, p. 126). The next section looks specifically at the use of photovoice in educational settings with youth and young children.

Children and youth photovoice research examples

The two examples that follow demonstrate the power of photovoice to give voice to the lived experiences of children and the adaptability of the method to meaningfully engage researchers as young as 3 years of age. Both examples asked children to consider their relationship with the natural world. The specific foci of the two studies, their implementation and products are different, but from them we learn how children define nature, and what nature means to them and how children are the experts of their own lives.

Photovoice and young children

In this example, we discuss the application of photovoice methodologies with young children at a nature preschool. This research project positioned young children as an underrepresented group who may have their voices and experiences inadvertently marginalized by the dominant group (adults). One goal of this project was to determine if young children (ages 3–6) had the developmental skills and cognition to engage in a photovoice methodology (Wang and Burris, 1997) and what accommodations would need to be made with the methodology to address the development abilities of this age group. As discussed previously, photovoice has traditionally been utilized with adolescents and adults, but not with young children. The project also aimed to understand how children viewed their learning experience at a nature preschool. Nature preschools are a relatively new type of preschool where children have extended daily access to unstructured outdoor play in wild, natural spaces. The goal of these schools is to combine traditional early child education learning with environmental education strategies (Bailie, 2016).

Preserve preschool: research setting and participants

The research setting of this study was a private preschool (referred to as Preserve Preschool) located at a private nature preserve. Two licensed preschool teachers led the class of 15 children (11 girls and 4 boys), who ranged in age from 3 to 6. The children attended 3 days per week for half a day. While there was a traditional classroom building, the teachers aimed to spend at least 65% of the day outside. Families are told to dress the children appropriately for the weather each day, even if it is raining or snowing. Outdoor time included free play on a playscape adjacent to the classroom building and guided hikes to destinations around the nature preserve. The playscape was a natural space with some specifically designed elements added to engage exploration with outdoor materials, such as rocks, logs to jump on, a sand pit to dig in, and an earthen tunnel. Examples of hiking destinations included a creek, pond, trees for climbing, wildflower field, sledding hill, and a stand of fallen logs. Even though Preserve Preschool focuses on environmental education, it meets state preschool educational standards designed to prepare children for kindergarten.

All fifteen children in the classroom participated in the study; however, one child chose not to complete the study. Consent of parents and child assent were obtained. In order to develop trusting relationships with the children, the adult researcher volunteered in the classroom for several months before implementing the study. All children were of Caucasian descent and were assumed to be from middle class or upper middle-class homes, as this was a tuition based private preschool. Most of the families were also members of the nature preserve.

Since nature preschools are a relatively new and atypical type of preschool setting, the goal of the project was to use photovoice to understand children's experiences at a nature preschool from their perspective, instead of imposing the researcher's adult lens on their experience. The photovoice project was for each child to take photos of their school experience over several sessions and then select photos for a book that told the story of Preserve Preschool. The tools for the photovoice process were iPod Touches and hard-bound blank books to create their stories of preschool. The study was framed with children as co-collaborators in the research, as the children took the photos (data) and determined which photos were most important to the story of preschool and why (analysis). The next section goes into detail on the photovoice process.

Data collection and the photovoice process

The following outlines stages 1–4, as described earlier in this chapter, which were utilized in this study. The researcher made adaptations only when absolutely necessary to meet the developmental level of the children. We begin at stage 1 in the photovoice process, establishing the research framework. Since group discussion with very young children about a research theme would be challenging, the children were shown a sample photo book that told the story of a hot air balloon ride that the adult researcher went on. The children were told they would make their own photo story books that told the story of preschool using iPod Touch cameras (hereafter referred to as cameras).

Photovoice is traditionally used as a social justice tool by populations with reduced power. This project was designed to support continuous improvement in Preserve Preschool and a high-quality learning experience for the children. The adult researcher explained to the children there would be benefits to the children and for the adult researcher by creating their photo story books. The adult researcher went on to explain Preserve Preschool was a very special kind of school and the project would help other teachers and the adults, like the adult researcher to learn more about their school and what is important at this type of school. The benefit to the children would be, their teachers would better understand what they like and don't like about Preserve Preschool. Then the teachers could make good decisions about activities they, the children, would enjoy. The adult researcher also explained the benefit to other adult researcher would be to understand how children can be good researchers of their days.

Once the children understood what they would be photographing, the adult researcher moved to training the children in how to use the cameras and the basics of framing a photo. All of the children appeared to have previous experience using a camera app on smart phones, so the children learned how to use these cameras almost immediately and helped each other in learning how to use them. All of the cameras were protected in waterproof, shockproof Otterbox brand cases.

In stage 2 of the photovoice process, child researchers take photos to document a particular issue/experience. The children were encouraged to take photos of whatever they wanted to best tell their story of Preserve Preschool. The adult researcher carried the cameras for the children when they did not want to use them. This allowed children to get them when they wanted to take pictures, without feeling burdened to carry them for the whole hike or during a free-play period. The adult researcher would remind children at the beginning of each day of the goal for taking photos and that she was carrying the cameras. However, the child researchers were not required to use the cameras at any time. The children took photos over 4 days during mid to late spring. The number of pictures each child researcher took varied widely in number and frequency of use was also wide-ranging. The range of number of pictures the child researchers took varied from 16 to 786 photos.

Stage 3 of the photovoice process, image selection and theme generation, typically begins with the community members sharing their photos with each other and discussing the meaning of each photo as part of a participatory analysis. Due to the age of the participants, this was adapted to meet the interest level of the young child researchers. After the four photo taking sessions, the adult researcher printed two sets of all the photos taken by each child and allowed each child to look at their photos. One set of photos was for the child to take home and the other set was saved for creating the photo book. The most significant modification to the photovoice process was needed here, as it quickly became apparent that while the child researchers were very proud of their photos and wanted to show them to adults and other children in the classroom, the children were not interested in looking at or hearing about each other's photos. Thus, the adult researcher adapted this step by sitting with each child separately rather than as a group to discuss their photos.

The next part of stage 3 is the analysis of the photos. To do this, the adult researcher and each child utilized a protocol for conducting the participatory analysis. The three stages of a participatory analysis process are selecting, contextualizing, and codifying (Wang, 2006). To support the selecting portion of the analysis, each child was given a hardbound blank book (28 pages/14 sheets), colored pencils and a glue stick. With the adult researcher, each child researcher sorted through their photos to select the ones that best told the story of Preserve Preschool to include in their book. For the contextualization step, the child researchers wrote a caption for each photo. Some children wrote their own captions, while those who were pre-writers dictated their captions to an adult scribe. The children each decided how to organize the photos in the books and how many photos to use overall.

The final step of analysis was completed by the adult researcher only. This step met the project goal to disseminate information about nature preschool experiences by children to a wider academic audience. The decision to have the adult researcher complete this step without the children was made after attempting a more traditional photovoice group discussion format with the children. Although the researcher tried to engage the children in sharing of their photos, the researcher quickly found the children did not want to engage in a group discussion and observed this level of categorization and abstraction was too developmentally difficult for the young children. Most preschool children are only able to recognize simple patterns (Copley, 2010) and the codification step of the analysis required the capability to discriminate complex patterns over a significant number of photos, therefore the adult researcher completed this step alone. Additionally, since this step was for the benefit the educational research community more than for the Preserve Preschool community, it was determined it would not have been the best use of the children's time. The adult researcher wanted to respect the children's curiosity in the project and not attempt to force them into a step they were not interested in.

In the final stage of photovoice, the presentation of findings, the child researcher shared their final products with their wider community. At the end of year school picnic that included families, the children received their final photo books to share with their families and take home. The children were very proud of their work and were excited to be able to share their creations with the teachers and parents.

The final product of the story book had direct benefit to the children, a central goal of any photovoice project, as it helped parents and teachers to more fully comprehend the experiences and priorities of the children at Preserve Preschool. The teachers were able to use the information from the children's photo story books in the development of the school curriculum. One example of implemented by the teachers, was having children participate in photo documentation of learning projects. Photo documentation is regularly used in preschools as a way to show parents and other stakeholders what children are learning. Typically, teachers take the photos and develop the documentation/display panels. After seeing the final photo books, the teachers started to include the children in taking the photos and developing the displays. The photo books also confirmed for teachers the importance of the hike to the students and ensured that this remained a central portion of the daily schedule. Student evaluations are not typically used in preschools and the photo book project allowed for concrete child feedback regarding the Preserve Preschool experience.

Photography results

The children took between 16 and 786 photos each. This includes those used and not used in the photo books. The number of photos each child used in their final books also varied from 3 to 22 photos. This corresponds with final percentages of total photos taken per child to photos selected for the book ranged from 3% to 28%. There were no noticeable sex or age-related patterns in the number of photos taken or percent used in the final projects.

Based on the photo included, the child captions, and discussion with the adult researcher while creating the photo story books, the adult researcher identified five important themes about the children's experiences at Preserve Preschool. These themes carried across the photo books created by the children and were not isolated to a small number of children. Each theme will be discussed in depth in the next section.

Theme #1

Children valued the nature experience at Preserve Preschool. Plants and animals were the subject of 43% of the photo/caption pairs used in the books. Many children also used specific common names, which were not always completely accurate, for the plants and animals in the captions. Also, the captions typically indicated positive feelings they had for the plant or animal. In one example of a plant photo the child correctly identified the plant species and indicated his affinity for the plant. Henry, age 4 captioned his photo, "It's green. It's pretty. Mayapple."

Theme #2

Children valued the social experience at Preserve Preschool. Photos with other people in them accounted for 35% of the photos used in the books. The people included teachers, classmates, parents, volunteers, and the adult researcher. This centers the social experience as an essential component of Preserve Preschool for the children. Matilda, age 4 selected a photo of her teacher and captioned the photo, "Ms. [Teacher]. She always thinks about trees. She loves rocks. Because I love her." These data show that while the nature experience was the most valued part of Preserve Preschool for the children, the social aspect was also very important.

Theme #3

The children viewed the hike as the most important part of the day. Images taken during the hike accounted for 66% of the photos in the books. Photos taken during the hike included photos of plants, animals, ground, sky, and other people in the class. Additionally, some captions, such as Celeste's, age 6, directly referenced the hike in her self-written caption, "I LiKe hiceng" [I like hiking]

Theme #4

The children valued the hike more than free play in the playscape. While each day began with free play on the playscape, only one photo of the playscape appeared in the final books. Observation of the children by the adult researcher indicated that the children enjoyed playing on the playscape, but its absence from the books indicated that this part of the day was not central to the story of Preserve Preschool from the children's perspective.

Theme #5

Preserve Preschool is not about the indoor classroom experience. While the children spent one-third of their day inside the traditional preschool classroom, only 9% of their overall photos were of the inside space and only 9% of indoor photos were used in the final books. This indicates that the indoor time is not central to the story of Preserve Preschool.

The themes found in the child researcher photos and captions gives voice to the children's value of the aspects of learning that were unique at a nature preschool versus a traditional preschool. The total number of images and book inclusion of the outdoor photos in wild spaces demonstrate how valued nature was for the children. The children's inclusion of specific flora and fauna and the social aspects of being in nature demonstrates the children's ability to represent layers of their experiences. The children's pride in their knowledge and ability to communicate their expertise through their books to the community reflects the value of photovoice to engage and give voice to even young children.

Children as co-collaborators in research

The preschool children proved to be highly capable in participating as co-collaborators, data collectors and data analysts in a photovoice protocol. All 15 children took photos in this study and 14 completed the entire process. The child who dropped out of the study quit at the photo book stage because she "loved" all of her photos and was uninterested in selecting those that best told her story of preschool. The adaptations to the four stages of photovoice discussed above were minimal. Stage 1 was shortened and included parents in the consenting and understanding the overall research goals outcomes. The child researchers engaged in the research framework when the adult researcher's photo story was shared as an example of their task. Other adaptations to the traditional photovoice process with young children included the elimination of the group sharing and discussion of photos. The children were very proud of their personal work but were not developmentally ready to engage in the work as a group project. Similarly, in stage 3, the children's developmental skills related to classification did not allow for the children to be involved in the final stage of analysis. To preserve the voice of the children as much as possible the adult researcher kept to descriptive codes derived from the children's word captions.

The children's proficiency at taking photos framed by the research task and their ability to make and explain decisions during selection and contextualization, indicate photovoice is a methodology that should be considered when investigating research questions that affect the lives of young children. Children are members of our society who have little choice about their daily lives and experiences, in comparison to the independence enjoyed by adult members of the community. This research demonstrated that the experiences of this marginalized group can be better understood through photovoice protocols.

Photovoice and urban youth

In this example, the authors share the use of photovoice for conducting a Youth Participatory Action Research (YPAR) research study. As the name indicates, YPAR is a sub-genre of PAR that is conducted specifically with young adults—generally young adults in their teens. The range of YPAR research settings is as great as the locations where collections of teens are found. Although it may be difficult to believe teens need greater voice, their volume does not necessarily equate to decision-making power. The pedagogy of YPAR and photovoice shifts studies around to embrace the youth participant's point of view. YPAR does this by relying on the people who have the closest relationship to the oppressive situation (Caraballo et al., 2017). Situated in YPAR is the argument that youth are in the seat of power and should engage as experts regarding their daily lives in the research process (McIntyre, 2008).

The youth environmental club: research setting and participants

This photovoice project took place during an afterschool environmental club in an urban high school. The research was an extension of work club had been engaged in focused on a local watershed. The group of middle school students, 12–14 years of age, and their teacher club leader worked with an urban watershed group to help clean up a creek portion. During their watershed the students talked. On several occasions the conversations included the importance of green spaces. As these conversations were happening, I, the adult co-researcher, became intrigued by their descriptions of the green spaces in their immediate neighborhoods. Their conversations about green space became the starting point for our photovoice research study. Formally our research question became: How do local urban youth, with limited access to nature, view the green spaces in their communities? Taking a youth participatory action research photovoice design (YPAR), the youth participants and adult researcher began to explore. The example that follows details use and power of a youth photovoice project for this middle school teacher researcher.

The photovoice process

One difficulty in all PAR, youth and photovoice is detailing the iterative nature of the research process, which although intentional and organized, flows and shifts in subtle ways. However, for the purposes of this chapter, we have aligned the process to the stages above. Some of the research framing of Stage 1 was described above. The participants were part of an established interest group of youth and their club leader and the focus emerged from questions that arose as part of their on-going activities. As co-researchers, we set out on a study to learn what we thought of our green spaces. It is notable in this example, issues of power and safety did not happen in this first stage, but they do come up later and will demonstrate the importance of these stage setting discussions at the start, even when the youth are photographing their own environments. Finally, in the stage setting, the audience for sharing the research was left implicit; the focus arose collaboratively from the group and met the purposes of the group. Although an external audience for the results is easy to imagine, it is sufficient to say the groups' interest and educational experiences met this step.

Taking pictures

Although the youth had access to phone cameras, these personal cameras were not used. The logistics of downloading select pictures and printing these for use was impractical. Further, the ethics of having the youth share pictures from personal devices when one of the co-researchers, the club leader, was a mandatory reporter created an additional power differential, and for a variety of other equity and security reasons personal digital cameras were just not an appropriate choice. Therefore, disposable film cameras were distributed to each participant. This added cost in both the purchase of the cameras and developing of the film. Surprisingly however, many of the participants had never used a disposable camera. As stage 2 also requires, training the youth researchers to use cameras was essential. Additional training included a discussion about the ethics of taking photographs in public areas. We agreed to take pictures from multiple angles of each green space. However, no direction as to content for the photographs was given. This was intentional. As a co-researcher, I did not want to bias my youth researchers in their photograph choices. Photovoice should gain the point-of-view of the participants (Wang and Burris, 1997). Then, they set out to take photos of their neighborhood's green spaces.

Understanding green spaces

At the designated date, the youth researchers returned their cameras and the film was developed so Stage 3 could begin. The analysis and knowledge generating stage of the photovoice process was intense. I transcribed these recordings and shared them with youth researchers. The convergence of the photo sorts and conversation transcriptions created a better understanding of the participant's perspective.

Wang detailed the SHOWeD discussion method; the youth researchers modified the analysis to process. We used a previously learned school science sorting method. Our sorting process started by selecting and discussing individual photos. The discussions that happened during the card sorts were recorded. Based on the discussions, the youth researchers began placing the images into big themes. The themes came from the youths' discussions; the adult researcher only asked clarifying questions. As co-researchers, we discussed each theme and clarified them by placing photos into smaller categories. We repeated this process several times,

reframing our themes and categories. Eventually, the youth choose two significant themes (1) nature experiences in city parks and (2) nature experiences in large parks outside the city as their final organizing system. Categories within the themes included photos with fields, hills, trash, flowers, trees, people, safe space, and reverence for green spaces.

An important note, and one that became an organizing feature of our research, occurred when one young woman in the group went rogue and took photos of a large state park located several miles away from the city. This action was unexpected because the youth participants had all decided to take pictures of our neighborhood green spaces. However, she stated, "There are no safe green spaces in my neighborhood, and my parents and I go to this location at least once a week." For her, this was her accepted green space. As discussed previously, the value of YPAR is the shift to accepting the youths' lived experiences and not reinforcing existing oppressive forces.

What we learned from our photovoice analysis speaks to the youths' urban life context. We discovered that our language and expectations, represented by our photo perspectives, depend on the green space's (park) location. We found the parks away from the city were revered. The youth said they noticed the beauty in such large green spaces. They felt more inclined to go and play in nature; splash in the creek. One participant referred to this as the "Real woods." In contrast, the parks in our urban communities had these hidden rules. Don't climb the trees! Stay off the grass! People in the city seemed more likely to litter in these small green spaces. Over and over, participants spoke about not feeling safe in urban parks.

Youth as co-researchers

As mentioned earlier this project did not have a stage 4, sharing results, as the nature of a club activity tied to a school calendar made this too complicated. There was not an explicit audience to share this research project with, but the power of the findings was real. These youth tell us, urban spaces are not real green spaces. Real green spaces do not belong to urban youth. Urban green spaces are dirty and have rules. Real green spaces are places of beauty and freedom. These contrasts could and should be shared with policy makers—city, county and state parks boards. City planners and police departments need to own the reality that urban youth do not feel safe in city parks. However, in this instance the learning experience was closer to home, for the youth researchers and the adult co-researcher.

Using the YPAR photovoice method with this group of urban youth was a learning experience that far exceeded my expectation as a researcher. Wearing the dual hats of a practitioner and a researcher frequently became a blurred line. As a researcher, I tried to be a keen observer with a systematic approach to the given situation. However, the practitioner's side of me struggled with already knowing my co-researchers and wanting to overlay my formulated ideas about urban culture and green spaces. This photovoice allowed me to hear my co-researchers' voices and see the world from their point of view. It required my overruling my biases and allowing the youth to lead the discovery.

In this example, we see how urban youth begin to notice and define their green spaces, a simple circumstance. However, this moment should be seen as the beginning of their self-consciousness, a pivotal moment when the youth begin to see green spaces as a reflection of how they are valued in the community at large. According to Freire, the highest level of critical conscientiousness is to be aware of one's assumptions and make a change or keep the current situation (Freire, 1970). This experience enabled the youth to realize the inequities of their surroundings.

Conclusion

The power of photovoice is its ability to give voice to marginalized communities, whether the communities are the women in rural China, girls in Indian schools, children of LGBTQ parents, or the preschoolers and urban youth discussed in this chapter. The intellectual foundations of photovoice arise from critical and feminist theory that seek to expose the unspoken structures that empower some while marginalizing others. The beauty of photovoice is in the power of the image to illuminate the unseen and obscured structures that support an unequal status quo. For many photovoice participants it is only when they come together to share their personal images that societal patterns are exposed, and the participants can act on their new knowledge.

How we define marginalized or oppressed may vary but as a participatory research method, photovoice gives voice and power to each group. Young children at a private preschool in the future may not suffer as an outsider group. However, now, as young children it is adults who observe and interpret children's actions in the world and decide what they like best. What we learned from this study was the preschool children were capable researchers and actors in their world. We learned that they valued their time in nature, they found beauty in nature, and there was freedom in wild spaces. We also learned the children found nature to be a social space, one to share and enjoy with others. The nature preschool was a safe space for the children.

In contrast, urban youth are frequent subjects of critical research and are often involved in YPAR and photovoice. As this case demonstrates, photovoice was a powerful mechanism for introducing these youth to the hidden structures that define their world, as they, like the preschoolers, explored their relationship with nature. The urban youth also expressed the beauty of nature and the freedom to be found in wild spaces. In contrast to far away wild spaces, the urban parks they had regular access to were not safe, beautiful, or places to be free. Our urban youth researchers stepped into the critical realm with photovoice. With photovoice, they were able to see their community in a new way.

The power of photovoice as a qualitative research method is in its adaptability to meet the needs of the researchers, no matter their age, education, or photography skill. When Wang and Burris (1997) presented the photovoice method, they had experienced its power to empower rural women to define and set policy around their health needs. Since then photovoice has been used across the world and across ages. We believe there is potential for photovoice to engage children, youth, and adults to explore nature and the natural world as we seek to develop an equitable and sustainable future for all.

Visual research and its place in research in education

During the last decades there has been an explosion of visual images largely due to the rapid development and availability of mobile phones with cameras for producing photographs and videos. There are billions of photos and videos shared on social media every day. The production of photographs in research with the help of mobile phones or traditional cameras has been slower even though there has been an increase of research using visual data and visual research methods. In recent years there has been a plethora of books and articles on visual data and methods (e.g., Beeli-Zimmermann et al., 2020; Holm, 2018; Leavy, 2019; Mannay and Pauweis, 2019; Pienimäki, 2021; Rose, 2016; Moss and Pini, 2016). At universities courses on research methods now often include a lecture on visual methods as well, but few research studies in education are so far based on visual methods. This chapter briefly contextualizes the field of visual research in education and then focuses on the use of participatory photography as a qualitative method when conducting research in education.

There are two major kinds of qualitative approaches used in visual research in education namely still images and videos/films (Prosser, 2000). Both visual research approaches have their roots in anthropology and sociology (e.g., Collier and Collier, 1986; Flick, 2002; Harper, 2000). The most common use of videos in educational research is videos of interactions in classrooms made by a researcher. There are several big international video laboratories often collecting videos about teaching and learning in specific subjects like language and mathematics (see e.g., Clarke's International Center for Classroom Research <http://www.iccr.edu.au/> and Klette's Teaching and Learning Video Lab http://www.uv.uio.no/ils/om/tlv_lab/). A trend gaining in importance in video-based research in education is the micro-analysis of video data. Micro-analysis usually focuses on one (or a couple if several cameras are used) participant's views or a particular type of interaction, setting or content (Rusk et al., 2014). Participatory video is still not common qualitative method in educational research but is becoming more common with young people outside of school (see also Burns et al., 2021). Much of the participatory video research takes the form of video diaries (see e.g., Pini and Walkerdine, 2011).

The still images can be, for example, drawings, cartoons, paintings, constructed social media images, or photographs (see e.g., Farber et al., 1994; Jipson and Paley, 1997).

Photographs used in research can be pre-existing from sources such as archives (Grosvenor, 2007a, 2007b), family albums (Mitchell, 2011) or magazines (Holm, 1994) or produced by the researcher or the participants particularly for a research project (Holm, 2018). What kind of photographs and approaches are used depend on the interest and research approach of the researcher and the purpose of the research. The commonly used photo-voice focuses on social change and social justice, where the participants photograph, for example, problems or injustices in their communities with the goal of community action (Sutton-Brown, 2014; Wang, 2006; Wang and Burris, 1997). Some researchers prefer a more arts-based approach (Knowles and Cole, 2008). Holm, Sahlström and Zilliacus (2018, p. 312) describe arts-based visual research as a continuum since "At one end, there is a strictly art-centered approach that emphasizes intertwining of making visual arts and doing research. At the other end are researchers who use visual art and artifacts as fruitful data, and who see arts-based research as a methodological tool."

Visual ethnography in education can take many different shapes (see Holm, 2018 for an overview), but most commonly photography (or occasionally video) is used as a method alongside participant observations and interviews. The photographs in this case

constitute data in themselves or can be used in connection with other data. Especially participatory photography with students producing their own photos is becoming more common in ethnographies in education.

Another approach and the most frequently used approach, where the researcher or the participants produce the photos, is the photo-elicitation interview. Photo-elicitation interviews are sometimes used alone or as part of a larger study as one of several methods. Most often it is the participants taking the photographs. Rose (2016) provides a thorough and detailed description of photo-elicitation interviews as an approach and a method. She describes them as a way to obtain different kinds of insights and to explore everyday life as well as empower participants since they are the experts on their own lives. Even though photos are taken for the interview and the photos and interviews analyzed together, the focus tends to be on the interview. The reporting and publishing of results focus on the interviews and describing the photographs, but usually do not include many of the actual photographs.

Participatory photography is similar to photo-elicitation, but still different since the focus is more on participants as co-researchers and on the photographs as a data source in themselves alongside other possible data sources such as interviews, observations, and participants' writing. It is a method familiar to students of all ages with mobile phones and an easily available method for all researchers in education. Participatory photography as a visual research method is discussed in-depth in this chapter and the production, analysis, and reporting of photographs as research data are discussed through an example of a study using participatory photography as a qualitative research method.

Participatory photography

Participatory photography is a way to engage the participants in producing data that they think is relevant for the research task presented by the researcher. Hence, the interest lies on the participants' views, perceptions, and experiences regarding a particular topic or their lived realities. Participatory photography can be a way to engage particularly the withdrawn and marginalized students (Cappello, 2005; Darbyshire et al., 2005; Lodge, 2009). However, it is not a method for only a particular purpose or group of participants like photo-elicitation interviews that focus on community action. If the researcher and the research participants do not share a common verbal language, participant photography also creates a common visual language (Veintie and Holm, 2010). The power differences between the participants and the researcher do not disappear, but are somewhat evened out, and the participants become more like co-researchers. The researcher still decides on the overall task and does most of the analysis and reporting. However, some analysis and reporting/publishing can also be done together with the participants (Holm, 2008a). If the participants are students, they can, for example, do the reporting of the results to the entire school. At times, participants also take more charge of the research task by interpreting the task in ways not initially intended by the researcher, even if the task is clearly stated (Croghan et al., 2008). Sometimes a participatory photography project is produced from the beginning to the end collaboratively with the participants as in Holm's study (2008a) conducted with doctoral students about what it meant to be a doctoral student.

Participatory photography is rarely used as the only data production method. Having photographs as the only source of data is too susceptible to misinterpretations as the photographer's intentions are not always clear to the researcher from only the photograph. Non-figurative and symbolic photographs in particular can be difficult to interpret. To avoid misinterpretations, captions for the photographs usually clarify the photographer's intentions (Holm et al., 2015). The photographs in participatory photography are rarely snapshots but are often carefully constructed to communicate the photographer's views and perceptions about the task assigned by the researcher. Often, semi-structured and open-ended interviews are used to complement participatory photography because the two methods complement each other by providing partially different kinds of information about or different perspectives on the same issues (Holm et al., 2015). In interviews, the photographs can be used to facilitate or prompt discussion about certain issues more like in photo-elicitation studies, or the focus of the interview can be the same as in the participatory photography assignment, without explicitly using the photographs. In Holm's (1997) ethnographic study of pregnant and parenting teenage girls a photography project was done parallel with participant observations and interviews. Together they showed the complexity of the girls' lives. The photographs told a story about the carefree and happy girls they wanted to be while the interviews were about their difficult life circumstances. In addition, the participant observations told the story of a strictly controlled and managed daily school life with rote learning while caring for their babies. Thus if participatory photography is used in ethnographic studies, it can be combined with participant observations and documents or artifacts in addition to interviews providing possibilities for data triangulation (see also Holm, 2018 for further examples).

Participatory photography research in educational settings requires substantial planning partially due to that research permissions are usually required by municipalities, research institutions and school due to that young students are involved. In addition, consent forms from guardians and teachers as well as consent or assent forms from students depending on their age. Consent forms need to detail the different uses of the photographs like used for analysis, publishing, conference presentations and in teaching. Confidentiality issues are of high importance when using photographs in research. The permission process can be quite demanding if so-called sensitive issues like bullying or racism will be studied. Depending on the situation consents can be given on paper or digitally via smartphones. For participants where everybody does not have a smartphone, students should be able to borrow phones or cameras from the researcher. For projects with students as co-researchers/photographers it is necessary to collaborate with one or several teachers. Teachers can help especially with informing and obtaining consent from guardians. As in ethnographic studies, the researcher must obtain the trust of the participants and have to be careful in creating alliances and cooperation.

Participatory photography research needs to be introduced and explained to students and here too teachers are key to giving class time for introducing a project to students. The process with students giving consent or assent and also the asking of consent from those being photographed is of utmost importance. In general, ethical principles need to be discussed throughout the process and the respect for other participants' photographs need to be emphasized if photographs are shown to others.

A participatory photography project usually starts with an introduction of the process and the topic of the study by the researcher, then students can discuss the topic in small groups to stimulate students' thinking on the topic. Students usually need two-three weeks to compose their photographs. A longer period tends to mean that students forget about their photographs. Today the photos are in most cases taken with mobile phones, which means that it might be necessary to set a limit to the number of photographs that can be submitted depending on the number of participants.

If the teacher allows, it is useful to have a time in class when participants write the captions for each photo. The photos with captions can be collected in class on a memory stick or submitted electronically directly to a safe repository depending on the circumstances. If a trusting environment has been created in the classroom students can view others' photographs and together look for themes and patterns in the photographs. Hence, a first analysis can be done with the students. If possible, it is also good practice to return to the students and schools with the research results if they can benefit the schools and students involved. However, here confidentiality takes precedence. If several schools and several classes are involved, it is possible to exclude the photographs of the school to be visited if the topic is sensitive or if it is possible to recognize someone. If other kinds of data such as interviews or participant observations have been collected, they can all be combined in the final analysis and reporting. However, in research with participatory photography the photographs are not mere illustrations, documentation or supporting data, but data in their own right that are analyzed both separately from and together with other kinds of data.

There are many types of analysis that can be done of photographs. [Rose \(2016\)](#) provides a review of some methods like discourse analyses and a psychoanalytic approach. However, in educational research the photographs are usually analyzed in the same way as the interview and observational data. Qualitative content analysis, thematic analysis or discourse analysis are often used, and photographs are categorized, organized into themes or discourses like the verbal data.

Several things can influence what is photographed, such as the time of the year. Projects in wintertime result in very different photographs than those taken in summertime. Outdoor photos are fewer and darker during the winter ([Holm, 2018](#)). If it is not possible for the participant to make the photographs, they want due to the time of the year (for example, Christmas traditions in summertime), it is quite common that the participant decides to use older photos not produced specifically for the research project. Another aspect that influences the subject of a photograph is consent rules. There are usually fewer photographs taken that include people since consent is needed from those photographed. This in turn leads to more symbolic photographs that are difficult to interpret without captions. Thanks to the possibility to give consent digitally via mobile phones, students are now slightly more likely to photograph people.

Participatory photography as a research method—a case study: high school students' awareness of privileges from living in a Nordic country

In this chapter on visual research in education, I will use a recent study on high school students' thinking about living in a Nordic country as an example through which I explore the use of participatory photography as a research method. I will use the example study to bring up important and interesting issues in participatory photography. The purpose of the overall study was to explore, in a cross-cultural way, how high school students in the five Nordic capital regions view living in a Nordic welfare state. In this chapter, the focus is on one of the study's research questions: Are students aware of the privileges afforded them by living and going to school in a Nordic country and if so in what ways?

The study was conducted using participatory photography with complementary small group interviews exploring students' perceptions in depth ([Pink, 2012](#); [Rose, 2016](#)). For the methodology I use my previous research on participatory photography, arts-based visual research, and visual ethnography as a foundation ([Holm, 2018, 2020](#); [Holm et al., 2015](#), [Holm et al., 2018](#)). The focus in this chapter is specifically on exploring how young people can express themselves using participatory photography as a research method. The overall research purpose is quite abstract and not easily answered. It required the students to reflect upon their own lives and societies. The focus is on students' awareness of and views on their privileges as all the Nordic countries—Denmark, Finland, Iceland, Norway, and Sweden—emphasize equality and equity in education and all aspects of life, although very little research has been done on young people's perceptions and awareness of their privileged positions compared to other young people in the world.

Our theoretical framework for the study was youth identifications ([Ahmed, 1996, 1997](#)), as we were interested in how the students positioned themselves in their respective countries. We used the term 'identifications' instead of 'identities' to indicate that we considered 'identities' as constantly developing and changing in relation to a sense of belonging to cultures, communities, and personal relationships ([Anthias, 2011](#); [Hall, 1996](#)). We were interested in whether students' identifications extended beyond the national borders to a more transnational Nordic level. Hence, the underlying idea here is to show that participatory photography can be used in studies with theoretical frameworks and research questions that are seemingly unconnected to visual research. Photographs are students' constructions of their views and thoughts and thus closely connected to their identifications (see also [Croghan et al., 2008](#)).

Even though young people today have a lot of freedom and many possibilities to form their own identifications, they are also constrained by inequalities such as racism, classism, and sexism. Various individual abilities and structural constraints interact and influence how young people's identities develop ([Anthias, 2011](#); [Gewirtz and Crib, 2008](#)). Schools, with their relationships and

structural opportunities and constraints, are crucial for young people's sense of who they are. Therefore, we chose to do our study in high schools. Furthermore, we chose to explore young people's views in all the five Nordic welfare states as they are often considered quite similar, but very little is known about how high school students view their own realities. We were interested in whether students perceived a sense of belonging or community also with the other Nordic countries. Did they think in terms of the Nordic countries as 'we' and 'us', in terms of 'us' (their home country) and 'others' (the other Nordic countries), or not at all in terms of 'us' (their own identification with neither their own country or the other Nordic countries) (Reay, 2009).

Methods and data

The participatory photography project was conducted in collaboration with one or two teachers in each school and sometimes in connection with another class activity. Participatory photography generally works best with a person on-site assisting in organizing the process. In this case, it was necessary to collaborate with teachers, since the study was conducted in five different countries. The project was integrated into class instruction in sociology, art education, social sciences, and in Swedish and Danish language classes.

We visited each school two or three times. We obtained research permission from principals via email (and in some cases also from school districts). The principal contacted teachers interested in our study. We then visited the schools to present and set up the study, as well as obtain written consent from teachers and students. All consent forms were collected electronically. We also emphasized that the students themselves could withdraw from the project without any consequences if they wanted to do so at some point. On our first visit, we held a brainstorming session with students about their thinking about living in the Nordic countries and about what they associated with or perceived as important regarding living in a Nordic country. We also brought up some basic issues about photography like light and distance, even though all of them were familiar with mobile phone photography. We also informed them about their responsibility to obtain consent of the person photographed to include the photograph in our study. People photographed could also give their consent electronically via their phones. We emphasized that the people photographed had the right to withdraw their consent for a photograph if they wanted to. This requirement of consent led to students not photographing many people. However, there were photographs, mostly of other students, that had to be excluded from the study because consent had not been obtained. Even if a person has given permission to use a photograph of them in the research and publications it is always the researcher's responsibility to consider which photograph that can be published since not only faces, but also environments and buildings like schools are identifiable.

Students were grouped into small groups to more easily keep track of their consent forms and photographs, as well as for conducting the small group interviews later. They were given 1–3 weeks, depending on the schools' schedules, for constructing their photographs. Students could take as many photographs as they wanted about what it meant to them to live in a Nordic country, but could only upload ten photographs (including captions) to the project's platform to keep the number of photographs for analysis manageable. Teachers helped organize the conversion of photographs to PowerPoint slides, which was done to make it easier to add captions. After a preliminary reading and analysis of students' photographs and captions, we returned to the schools to conduct the interviews in small groups (3–5 students). The semi-structured interviews about what it meant living in a Nordic country lasted approximately half an hour. In the small group interviews, students could choose to discuss their photographs further or discuss other Nordic issues as a group. The small group interviews brought up new issues, showed that there were differing views, and provided more extensive descriptions about some issues related to the photographs (like the quote on page in section [Living in a Bubble](#)). After doing a thematic analysis (Braun and Clarke, 2021) of the photographs and the interviews we returned to the schools a third time to present the results to the participants, but in some schools many other students and staff also participated in the presentation of the results.

The data for this chapter consist of 700 photographs, taken in 2018, and the accompanying 33 small group interviews. A total of 178 upper secondary students from seven upper secondary schools in metropolitan regions of Copenhagen ($n = 33$), Helsinki (three schools, $n = 61$), Oslo ($n = 30$), Stockholm ($n = 24$) and Reykjavik ($n = 30$) participated in the study. The average age of the students was 17. The school language and home language were the same for most students, but in two schools there were many students with another ethnic/language background than Danish, Finnish, Icelandic, Norwegian or Swedish. There are three schools in Helsinki as Finland is a bilingual country, and thus one school was Finnish, another Swedish, and another Finnish school was included that represented more ethnic diversity.

There are a variety of methods that can be used to analyze visual images, but for photographs produced by participatory photography qualitative content analysis, discourse analysis or a thematic ethnographic approach (Holm, 2018; Rose, 2016) are common. In the Nordic study, a thematic ethnographic approach was used with the purpose of exploring whether major themes emerged. All photographs and captions were viewed and read several times (Keats, 2009) and then grouped into categories like 'nature' and 'equal rights'. It was necessary to read the captions together with the photographs to understand students' intentions with the photographs. The categories were then further analyzed. For example, the category nature was broken down to subcategories like clean nature, accessible for all, and general nature photographs. After many readings/viewings, privileges emerged as a theme stretching over multiple categories, like clean and accessible nature, rights, welfare state advantages like high-quality education, and infrastructure. A similar analysis was conducted of the recorded and transcribed group interviews. Thereafter, the themes from the photographs were compared to the themes of the interviews and combined when they overlapped. One of the major results of the study was that students in all five Nordic countries perceived that they were lucky to live in a Nordic country for various reasons that are detailed in section [Students' Perceived Privileges Regarding Living in a Nordic Country](#).

Students' perceived privileges regarding living in a Nordic country

There were six subthemes emerging under the theme of perceiving oneself as privileged due to living in a Nordic country. Even though there were variations between students from the different countries, the themes discussed below emerged in the

photographs from all the five Nordic countries. The subthemes are related to nature, welfare state privileges, equality, freedom and safety, carefree youth as well as a critique of what some of the consequences might be of living in a privileged bubble.

Nature

Interestingly, and somewhat surprisingly, the clean and beautiful nature, easily accessible for all, quickly emerged in the students' photographs as one of the important privileges of living in a Nordic country. Today's youth is often thought to be more occupied with and interested in mobile phones and social media, but the students in all countries were very much aware of how privileged they were by living in countries with a lot of clean and beautiful nature nearby (Fig. 1).

Students frequently pointed out that in the Nordic countries, people spend time outdoors regardless of the weather. With appropriate clothing, it does not matter if there is ice and snow, rain, or sunshine (Fig. 2). Students expressed an appreciation for having been taught to enjoy spending time in nature and the beauty of nature. Clean lakes and forests full of edible things were also regarded as part of being privileged with close access to nature (Fig. 3).

Fig. 1 Nature is our thing (I=Iceland).

Fig. 2 In the Nordic countries we have a lot of forests (or woods?) and nature where we happily spend time (N=Norway).

Fig. 3 It is so cool that we can pick berries and mushrooms in the woods since our nature is so clean (F=Finland).

Welfare state privileges

Many students brought up that living in a Nordic country meant living in a welfare state with all its advantages. The social security was brought up by students in all the countries. Most important was the high-quality and free education system. Education is free from early childhood education throughout tertiary education. "I think we've got one of the world's best school systems and we've also got free education, so that will give us every option in the world." (D = Denmark) Photographing high-quality education and

Fig. 4 I've had many many many many many surgeries and I'm still (in the same place) in the school system as my friends. I think we have the privilege that we can do that. Because not in every country you can. In every Nordic country, this is possible (I).

at the same time protecting the confidentiality of the school, students and teachers is difficult. Consequently, photographs of schools are not included in this chapter as they may enable identification of the schools.

With the help of a school system equipped with technology and a well-functioning healthcare system, students do not fall behind in school even if ill. Access to technology is also emphasized in other contexts as a privilege (Fig. 4).

Another student said, "Thanks to the Nordic welfare states, people have equal possibilities to live a good life and to choose the kind of life they want to live." (D = Denmark).

A well-functioning infrastructure including good public transportation was appreciated, especially because students in the Nordic countries are largely dependent on public transportation to get around (Fig. 5).

Especially in Denmark, but also in most of the other countries, bike lanes make biking the major alternative to public transportation for young people. Many students bike to school, as seen in Fig. 6.

Interestingly, the availability and priority of both healthy food and clean water were also connected to the privileges of the welfare state (Fig. 7).

Fig. 5 Good public transportation. The subway. The development of the infrastructure is good (S=Sweden).

Fig. 6 It is Nordic to bike everywhere and keep nature clean (D).

Fig. 7 Clean water.

Equality

Students in all countries perceived that equality is of high importance and were very proud of the fact that equality is an emphasized policy and characteristic of the Nordic welfare state. Gender equality was emphasized through photographs of fathers taking parental leaves to care for young children and also by expressing respect for women (Fig. 8).

As one student said:

"As soon as a man disrespects a woman, everyone is like "What the fuck did you say?!". Everyone is standing up and say: "This is not right!". And maybe you cannot see this in every country." (I)

Fig. 8 Gender equality is Nordic (man with a baby carriage) (D).

There were many photographs of rainbow flags, parades and even houses indicating equality for sexual minorities (Fig. 9).

A student in Iceland explained the support for the gay pride festival as “it is just like a family day, a family holiday, and everybody joins in to show our support and we support everything and everyone.”

Also, children’s rights and the rights of people with special needs were mentioned (Figs. 10 and 11).

Students pointed out that the Nordic countries have a Christian heritage, but that today there is freedom of religion (Fig. 12).

Fig. 9 Everybody is accepted (Fswe = Finland Swedish).

Fig. 10 Children have the same rights and value as adults (F).

Fig. 11 It is Nordic to be disability friendly and to accept people as they are (D).

Fig. 12 Freedom of religio (F).

Freedom and safety

A society emphasizing equality and equal rights is also connected to freedom and safety. Students in all countries talked about the freedom and safety in the Nordic countries, but the Icelandic students insisted on Iceland being the safest (Fig. 13). "It's a stress-free environment. We don't have an army, and the cops don't have guns, or they have guns now, but they have only once fired it ... not having to worry about some things that people in other countries have to worry about."

Fig. 13 Our environment gives us a sense of calm and security (F).

Another student pointed out that “It is calm and nice in the Nordic countries, sometimes so nice that we forget about the places in the world where it isn’t as nice.” (D)

A student from Finland said “I feel safe to live in Finland. You can walk on the street without being scared and you can freely express your opinion.” (F)

However, there were also some critiques of not taking advantage of the freedom, but instead everybody follows the familiar path with few going their own way (Fig. 14).

Fig. 14 We are all very similar in the Nordic countries. We are all walking in the same direction (D).

Fig. 15 Going to sunny places on vacation (N).

Carefree youth

In photographs and interviews, many students expressed that they could live a carefree youth. They know their education is free and that they can take a sabbatical year after finishing high school and still get back on track to education and employment later due to the social welfare system. After school, most of them socialize with friends or participate in hobbies. Only in Iceland did some students say they work after school to earn money for themselves. Norwegian and Danish students in particular described how they can afford to frequently go on vacations abroad (Fig. 15).

However, the carefree upbringing and a privileged life was also criticized by some students. As an example of the backside of a carefree youth the partying and drinking culture among young people in the Nordic countries was brought up and photographed by students in all countries.

Living in a bubble

The freedom and safety in the Nordic countries are questioned by some students as creating societies where homogeneity is emphasized and where the majority norm should fit everybody, even though the Nordic societies are at the same time argued to be open and where people can be themselves (Figs. 16 and 17).

Living in a safe and privileged bubble was brought forth and critically analyzed by students in Denmark, Iceland, Norway and the Swedish-speaking school in Finland. The privileges and sense of freedom and security can make people care less about others. Two students expressed the feeling of living in a bubble as follows:

"The Nordic countries are like bubbles of safety. There may be many tragedies outside the bubbles, but the bubbles remain secure." (D)

"I was thinking about the Nordic countries as one big bubble of security. Outside Scandinavia so many terrible things can happen, but it will remain secure inside our countries. And I feel like that's a big part of our identity that we don't have a lot to be scared of. But maybe for that reason, we are a bit like 'them and us', so it's like inside the bubble, we are taking care of each other, but we don't think as much about outside the bubble because we know it's secure inside the bubble, so we stay there. (D)

A student from the Swedish-speaking high school in Finland summed up their, and many other students', privileges in the following way:

"Being a nordbo (= person from the Nordic countries) is actually being part of the top one per thousand of the whole world, I'm set for life. I don't actually need to do anything that requires like a whole lot of anything, and I'm still going to live a significantly better life than 99.99999 percent of people. I was just born into this. I was just born into a little, nice, white family like this that lives in Finland, and I'm a white man, so I, like, have it all. I've been raised in a good family, a good environment, I've always had it well, good, I've gone to school for free, been educated, speak multiple languages fluently, like know multiple kinds of things that other people educate themselves their whole life for. I'm 19. I keep better track of, like, the whole world than the majority of the world, and that's *only* because I've been born into this. Nothing else. It's such a huge blessing, to live here. And I don't have any interest in moving away. Like sure, I want to travel the world, see what it's like in other countries. Maybe live somewhere else a few years. But I'm probably going to die here. I've already traveled enough to be of the opinion that nothing better exists. Like, you know, it's much more equal, safe, and good on average in Finland or in Sweden, Norway or Denmark, whatever, than in other countries. And like, I'm cool with that. I'm going to live here, actually, I don't have a reason to move away from here." (Fsw)

Fig. 16 People in the Nordic countries are relatively homogeneous. We are all alike and could as well come prepackaged in IKEA boxes. Build your own NORDBO! (Fswe).

Fig. 17 We live in our own small, privileged world (D).

Concluding points of interest in participatory photography

When analyzing photographs, it is important to look at what is missing since it can be equally important as what is included. In our study, for example, despite two ethnically diverse schools included in this study, there was only one photograph referring to ethnic or racial diversity, namely a photograph of two Somali girls with the text “Odd to belong to two worlds. Between two worlds.” In addition, even though there were photographs about the importance of equality, quality and equal access, there were no photographs about inequality, discrimination, prejudice, racism, or sexism. Equal opportunities were mentioned, but it was never questioned whether equal opportunities are the reality in the Nordic countries. For example, gender equality is photographed and mentioned, and gender equality is the official policy. However, generally men take shorter parental leaves than women do, and there is a substantial difference in women’s and men’s earnings. The reason for the lack of these kinds of photographs may be due to how the task was presented or that students did not feel comfortable with bringing up the more problematic aspects of living in the Nordic countries in the school context. It is also possible that it is difficult to photograph problems like prejudice and racism. The absence of a more critical view examining if privileges are afforded everybody living in a Nordic country independently of race, ethnicity, gender and social class would need to be investigated either by adjusting the participatory photography task by asking

students to focus specifically on inequalities or by more in-depth interviews. However, students in other studies have relied on symbolic photographs for things that are difficult to photograph, such as micro-aggressions against language minorities (see Holm, 2018; Holm et al., 2015). These kinds of symbolic photographs are usually discussed further in interviews, but the photographs tend to be a way to bring the difficult issue up for discussion. What is missing and absences are known to be difficult to photograph. Sometimes the photograph shows the presence of something or someone, while the caption explains that what is shown is missing. For example, in a study of doctoral students' daily life international students submitted photographs of their families and their children, which lead the researcher to interpret the photographs to mean that their families are important in their daily lives. However, the captions explained that they missed their families daily and the photograph of the families showed whom they missed (Holm, 2008a). In the Nordic study it is evident that students have photographed things that are currently relevant for them and their lives like bikes, buses, and health care but not, for example, the equal access to high-quality day-care.

In the interpretation of the photographs, there are several layers of interpretation that need to be considered. First, the photographs are by themselves the students' interpretations of the task given and of their realities. My interpretations as a researcher are influenced by my interpretation of the task given by me, as well as by my academic and personal background, which in this case includes my Nordic habitus, experience living in a Nordic country, and familiarity with all the Nordic countries and capitals. Important questions to ask are whether my Nordic habitus pushes me to interpret the students' photographs and captions as more realistic and truer or naïve. In what ways are students' photographs expressions of their national and Nordic habitus? Mannay (2010) sees a researcher's common habitus with the participants as decreasing the distance between them but also that there is a risk for making faulty assumptions about having a better understanding of the participants' photographs. For both Bourdieu (1990a) and Sweetman (2009), photographs work well in research to describe abstract notions and perceptions as well as what participants take for granted. The final interpretation is made by the viewer or reader of the photographs and texts, and their habitus may influence their interpretation. Hence, the photographer has no guarantee that the photograph is interpreted as intended by the researcher or the reader of a published photograph (Holm, 2020).

Photographs are one kind of qualitative data in a study and are valuable on their own and do not need to be translated into text, instead they interact with the text. The researchers' translation of photographs limits the viewers to the researcher's interpretation of the photographs. As part of the data, photographs can be included in the reporting of the results and in relation to other data (see Holm, 2008b; Pink, 2012), as shown in the examples from the Nordic study. Publishing photographs as part of the results has become more common thanks to the increase of online journals. Still, in most cases the photographs are published as very small images, which diminish their power to speak to the reader. Further, photographs printed in articles and chapters are almost always printed as black-and-white photographs, something that most of the time changes what and how they communicate. Colorful photographs, such as the bowl of colorful blueberries (Fig. 3), does not send an equally powerful message when the photograph is printed in shades of gray.

Most people encounter a lot of visual images, photographs, videos, games, emojis and other visual messages daily. Our communication is not only oral and written, but also visual. In order to connect with research participants, especially with young students, including a visual method is often advantageous. In participatory photography, the information emerging from the photographs is often surprising (see Holm, 1997; Holm et al., 2018). In this Nordic study, we were surprised that, although all the students attended schools in urban or suburban environments, there were surprisingly few photos from urban environments and very many from natural mountain, forest, or lake environments. Nature is, of course, also mentioned in interviews, but I as researcher would not have understood the extent of students' appreciation of and importance placed on a vast and clean accessible nature as a major privilege of living in a Nordic country. In conclusion, participatory photography as a qualitative research method brings forth the participants' views and knowledge by leaning on the participants' own data production.

Documents are a seen-but-unnoticed part of our everyday lives. Whether physically held in your hand, viewed on a computer screen or scrolled through on a mobile phone, they are staple elements of all areas of our lives. They shape our thoughts, actions, talk and writing. We consume them in vast quantities, routinely refer to them in conversations, as well as produce them. However you conceive of them, they are essential to the formation of our contemporary societies and institutions.

Document-based research in qualitative educational research, as in all areas of the social sciences, is a relatively small-scale enterprise. The notable exception is historically orientated research, where—given the lack of living sources of evidence—the document is the potentially the only source of evidence. Also, the practice of “reviewing the literature” relies on collecting, analyzing and speaking about a range of documents. Commonly, this is often relegated to the front sections of articles and reports, prior to a primary focus on the analysis of interviews, conversations in focus groups or observations of the interactions of others, but rarely explained as a practice itself.

In this chapter, we will begin to explore some of the variety of ways that qualitative researchers have actively sought to engage with documents as a central part of their research practice. We will explore some more general issues about conducting research on and around documents. We will then focus on two main areas. Firstly, we look at research that focuses on the substantive content of documents—the relatively new area of systematically reviewing qualitative research articles—and the more discursive work that looks at how documents, be they newspaper articles or policy documents, creates specific versions of the world. Secondly, we will look at research that focuses on the situated use and creation of documents—how interview-based and ethnographic studies have also looked at the place of documents in the lives and routines of those they study and on the more ethnomethodological work, that seeks to describe in detail the practical ways that documents are used and created in specific instances of interaction.

Approaches to analyzing documents

We will be using the term documents to refer to both paper-based and digital texts. This includes both the written elements of texts alongside the extra-textual elements—images, photos, graphs, diagrams—that are routinely embedded in documents. The post-structural and post-modern turn in academia has led to an expansion of the meaning of the term “text”, to include buildings, bodies, clothing, alongside artifacts, devices and other aspects of material and technical culture. Simultaneously, interview transcripts, field notes and video-recordings are referred to and analyzed as “texts”, but we will not focus on either of these genres of work here. Instead, we are concentrating on four relatively distinct areas of work around documents (See [Table 1](#)). This table provides an “at a glance” comparison of the four analytic methods in terms of their general focus; a more descriptive account of their analytic focus; examples of their typical research questions; the data collected to answer these questions; the key methods involved in data

Table 1 Approaches to analyzing documents.

	<i>Meta-synthesis</i>	<i>Discourse analysis</i>	<i>Ethnography</i>	<i>Ethnomethodological ethnography</i>
<i>Focus</i>	<i>Content of documents</i>		<i>Documents-in-action</i>	
Analytic focus	Inter-textuality	Language & inter-textuality	Social interaction & organizations	Language & social interaction
Typical research questions	What is the evidence for a specific topic?	What versions of the world do documents create?	What part do documents play in the organization of a social institution?	How do documents shape (and are reflexively shaped by) ongoing social interaction?
Data	Academic outputs	Any	Any	Any
Method	Collect documents	Collect documents	Collect documents, field notes, formal and informal interviews	Collect documents, field notes, interviews, audio-visual data
Methodologies	Meta-ethnography, meta-synthesis, thematic synthesis Qualitative synthesis	Discourse analysis, critical discourse analysis, foucauldian discourse analysis, semiotics	Interactional ethnography, grounded theory, phenomenology, symbolic interactionism	Conversation analysis, ethnomethodology
Results	Synthesis of findings of a collection of documents.	How documents construct and reflect a specific version of an argument, truth, social identities or institutions.	Use, role and function of documents in specific organizational contexts.	Use, role and function of documents in specific interactional contexts.

collection; the methodologies often related to these approaches; and the type of results they each produce. These four analytic approaches will each be described individually in greater detail below.

Analytic work on documents can be loosely divided into two areas (see [Table 1](#), “Focus”):

1. Work that focuses on the actual textual and extra-textual content of documents (meta-synthesis and discourse analysis).
2. Work that focuses on the use, role and function of documents in interactional and organizational settings (ethnography and ethnomethodological ethnography).

The first focuses on the document as an object in its own right, as an “orphaned” or “docile” text, as a container of knowledge. Such work forgoes empirical observation of how people actually read, refer to or use the documents in question. The second area is primarily observational, seeking to understand how documents are active agents in organizational and/or interactional life. Obviously, the same topic can be approached in multiple ways and within the same project. So, with a research project on say, student evaluations of lecturers, you might focus on: the written comments students give (via discourse analysis of these evaluation forms); how results of these evaluations are fed-back on web-sites, internal memoranda or official reports (via discourse analysis of a range of types of documents); how lecturers introduce, distribute, collect and read such forms (via observation in classrooms and offices); what students, lecturers and managerial staff think is the value of such documents (via observation of lectures and meetings and interviews with people); the role of such evaluations in creating institutional change (via observation and interview); etcetera.

Whatever approach people take, and irrespective of the methodological traditions they follow, the practical work of analyzing data related to documents closely echoes that of all forms of qualitative research. So, the data—be it documents, interviews, field notes or audio-video recordings (see [Table 1](#), “Method”)—will be subject to some form of sampling, as it is collected it will be coded, and some version constant comparison method and (ideally) deviant case analysis undertaken, as well as some level of reflection on the role of the analysts in the process.

The analysis of documents is also related to the research tradition of content analysis (see [Krippendorff, 2018](#); [Weber, 1990](#)). In this, researchers gather specific documents, then establish a coding frame which is then applied to the documents to count the number of times particular words, phrases or themes are used. This enables descriptive and statistical findings to be established (see for example [Bozkurt et al., 2015](#) for a more statistical style of work). However, this is often seen by qualitative researchers as a relatively limited, albeit systematic approach, in that it overly predefines the key aspects of analysis alongside often removing words and phrases from their context (see [Paradis and Whitehead, 2015](#), who blend deductive and inductive approaches, as well as [Hartley and Morphew, 2008](#) for more emergent, descriptive, style of work). Some researchers use content analysis alongside other more discursive methodologies, in part to gain a general overview of their data, although this is not discussed here.

Meta-synthesis: documents and creating (new) knowledge

The social, medical and political sciences have seen the rise of “evidence-based” policy and practice over the last 30 years. Education research has been central in this trajectory, and this shift has not been without its critics (see, for example, [Hammersley, 2007](#)). The growth in systematic reviewing and meta-analysis has also been significant in prescribing a new format for the textual analysis of research (see [Table 1](#), first column). In relation to reviews of non-experimental research, [Noblit and Hare’s \(1988\)](#) work on “meta-ethnography” has been influential. They sought to combine the findings of six ethnographies on the impact of desegregation on

urban schools in the US in the late 1970s. They translated the relatively diverse findings of the case studies into a general theory about the impact of desegregation. Following this inter-textual work, a range of approaches to synthesizing the findings of qualitative research have emerged. They have been referred to under various terms including: metasynthesis (Sandelowski and Barroso, 2006), critical interpretative synthesis (Dixon-Woods et al., 2006a) and thematic synthesis (Thomas and Harden, 2008). They all rely on insights from Nobilt and Hare's (1988) original work, and all seek to move beyond simply aggregating and summarizing findings from qualitative research papers to actively create new conceptual models or theories and to provide evidence for future interventions.

As with quantitative systematic reviewing, this qualitative synthesis work involves searching, evaluation, data-extraction and presentation. However, given the non-numerical nature of the findings they have adapted each stage in the process. Importantly, the process echoes and draws on key ideas from how you conduct empirical, primary, qualitative research. For example, when searching the existing literature, you seek a broad range of heterogeneous studies, purposively sampling studies that cover a range of approaches and findings to the substantive topic of the review. Scruggs et al. (2007) work on co-teaching used a range of databases, reviewed the reference lists of included papers as well as those papers that had cited the work, alongside handsearching key journal in the field. You may additionally engage in further rounds of sampling to find further documents that challenge or extend your initial findings (see Dixon-Woods et al., 2006b). The evaluation of the quality of studies is also complex, in that there is no hierarchy of evidence available for qualitative research. In this way, inclusion and exclusion criteria and judgments about quality are more flexible with an initial focus on how relevant the article is to the topic and to the development of the synthesis, and only papers deemed to have major flaws are rejected at the outset. Scruggs et al. (2007) used such a broad approach of quality appraisal, rejecting a checklist approach. They report "employing ... considerations", that focused upon processes and outcomes, that:

[d]ata were systematically collected and recorded, multiple informants and/or data sources were obtained, disconfirming evidence was considered, and the conclusion was reasonable and appropriate based on the data collected.

Scruggs et al. (2007, 398).

They also note that all studies had already gone through peer review, be that through acceptance for a journal or thesis examination. Currently, we have a range of approaches to judging quality that draw upon and combine the key aspects of various quality guidelines that exist.

With data-extraction, the focus is on collecting data that enables the researcher to outline the key ideas, concepts and themes within the article. This also includes extracting verbatim quotes from interviews, field notes and other sources alongside summarizing key aspects. The final stage of synthesizing the data shifts the focus beyond just summarizing the extracted data, to producing explicit interpretations. Again, this process is similar to that undertaken in analysis of primary data in qualitative research. The extracted data is then coded in detail, coded sections are compared and contrasted, and you generate a coding frame which outlines the main themes and issues and relationship between them. These recurring "lines of argument" (Nobilt and Hare, 1988) are drawn from both your new conceptualization of the original data together with some of original concepts used in the articles. Ong et al.'s (2020) synthesis of work on women of color in undergraduate engineering education, that included both mixed methods and quantitative papers as well as qualitative work, used both deductive and inductive coding framework, that they developed through an iterative process. Their abductive analysis developed four analytic themes—interest, motivation, and self-efficacy; social pain; navigation; and support entities—with further, detailed dimensions to each area. For example, one of the four dimensions, "being the only one" of the theme "social pain", outlines the sense of isolation, loneliness, and anxiety that can emerge "from being the only one of their gender and/or race/ethnicity" (596) in an engineering classroom.

This style of working with documents is still relatively young, much of the work has been undertaken in relation to health-related topics, and currently we have a range of complementary methods and methodologies (e.g., scoping reviews, Arksey and O'Malley, 2005, and rapid reviews, Khangura et al., 2012 and see Gough et al., 2012, for a useful overview). What they do share is a concern to compare, combine and critically interpret the findings of different qualitative articles. In this way, they attempt to generate new micro- and meso- level conceptual models of the topic of the review.

Discourse analysis: documents create realities

Rather than see the documents as neutral sources of information to be searched, evaluated against some external quality criteria, and then the data abstracted from the context, another way that researchers analyze documents is to undertake a relatively close and detailed analysis of the language and meaning within the document (see Table 1, second column). This style of research, known as discourse analysis, focuses on how documents produce specific versions of reality. Within this approach, language (written or spoken) is never treated as a neutral, transparent, means of communication. Instead, language is understood as performative and functional. So, for example, describing something as a "systematic review" instead of as, say, a "review of the literature" or a child as "gifted and talented" over, say, "bright for their age" does specific work, and directs thoughts and actions. Researchers

are interested in the specific versions of the world that documents produce, the effects they have both on the potential reader and on the wider culture, society, and institutions.

Within this style of research, the focus is on how words are used. Methodologically, there are two main research trajectories – discourse analysis (Potter and Wetherell, 1987) and critical discourse analysis (see Fairclough, 2013; Rogers, 2011)—although in practice they often somewhat overlap. Whatever approach is taken, when studying documents in this way one is interested in the rhetorical work of the text, how the specific issues it raises are structured and organized, and how it constructs a specific version of the world.

You might try to understand how the document seeks to persuade someone about the authority of its understanding on an issue. So, for example, you might focus on the range of sources of knowledge and evidence a document draws on—so within a newspaper article you may have verbatim quotes from leading practitioners or academics, references to policy documents or academic articles, and report on conflicting sides of the argument. Such intertextual work helps build the factual status of the account. Moreover, you might focus on the forms and modes of language, knowledge and evidence that are employed. For example, Setyono and Widodo's (2019) work on the (re)presentation of multicultural values in an English as a foreign language (EFL) textbook, closely analyses parts of an Indonesian Ministry of Education and Culture-Endorsed EFL textbook. They show how both visual and verbal elements of the text—including the specific cartoon images used, as well stories and situations used as examples—seek to encourage readers to see and value pluralism. Centrally, such work is trying to make sense of how the document produces a specific argument, the positions it takes in relation to a topic alongside the other alternate or contradictory positions that are excluded or silenced.

Another central question asked of documents from work in this tradition is how are specific ideas, practices, or identities produced, sustained or negotiated within texts? Some researchers seek to understand and describe the historical trajectory of the contemporary ideas we all currently take for granted. People often work quite closely with some of the writings of the French philosopher Foucault (1977). One of Foucault's interests was in how specific discourses, specific formations of what he called power/knowledge (e.g., medical, psychological, or pedagogical discourses) produce, shape, and enable specific subjects (e.g., attention-deficit/hyperactivity disorder (ADHD)-diagnosed children) and specific actions (e.g., advising parents to get children tested; prescribing medications like Ritalin). For example, Rafalovich (2004) has focused on the conceptual antecedents of the contemporary diagnosis of ADHD. Drawing on articles and books from 1877 to 1929, Rafalovich looked at the trajectory of three concepts—"idiocy"; "imbecility"; and "encephalitis lethargica"—and was able to reveal the initial attempts by medicine to establish an organic basis for children's apparently immoral, or unconventional behavior.

Such histories of the present remind us that what we take for granted often has complicated and esoteric beginnings. This style of work may lead to us to the question why exactly we act in "just this way" or why certain groups of people have the knowledge and power, i.e., authority, to interpret, speak about and act upon others. Importantly, it seeks to map the trajectories of these discourses, to outline the specific strategies that led to our present state of social organization as well as those that were rejected or seen to fail. Obviously, given its historical nature, this style of work often uses documents to explore specific topics or questions. However, such histories may focus on something that has emerged in the recent past and may also rely on other forms of data—a multimethod approach. Therefore, in Rafalovich's (2004) study of ADHD, he also undertook interviews with parents, children, teachers, and clinicians. In addition, rather than focus in great detail on a small sample of texts these studies can instead focus on a broad range of texts as they try to show the styles of thought as they emerge, consolidate, and compete across and between texts often over a large time-scale. Importantly, such work asks: "what are the assumptions in specific documents?"

Ethnography: documents, interactions, and organizations

The ethnographic approach to documents (see Table 1, third column) can cover a broad spectrum of activities and sites, although it routinely focuses on the use, role, and function of documents in the context of schools. In general terms, such work seeks to combine a more micro-focus on moments of social interaction with and around documents in a range of classroom settings, a meso-focus on the organizational ecology of schools and a macro-focus on broader community, policy and political factors.

One of the most obvious roles documents play in education is reading, especially reading in class. Ethnographers are not really concerned with reading in terms of the cognitive processes involved and do not understand it as simply as a monadic activity—that is, that reading can only be understood as something people undertake in isolation or even individually. Rather, they focus on reading as a practice situated within and related to the broader contexts of classroom activities and organizational cultures. For example, the video-based ethnography of literacy by Castanheira et al. (2000) demonstrates the situated roles and relationships that people can establish around documents. They offer two contrasting cases. They show how in one moment, a teacher positions a specific workbook as the authoritative source of knowledge and how the student and their partner are positioned as potential resources for defining and completing the task. Whereas in a different lesson, a teacher directly engages with the student, asking questions, encouraging them, draws a graph on the student's paper, etc. In this context, the student and teacher collaborate on the problem at hand, thus the student is positioned as central in producing knowledge with the workbook positioned in a supporting role. Such ethnographic work also seeks to make sense of such situated reading work within the organizational ecology of education. Therefore, you may compare the use, role, and function of workbooks over time, over single classes, over different students, or over multiple subject areas; you may research the background of the teachers or how the workbooks get selected as well as the

schools or regional policies around such workbooks. In this way, such research focuses on the embeddedness of reading documents in relation to both students' classroom interactions and their broader educational and social worlds (Green and Meyer, 1991).

As education is bureaucratically organized—and routinely involves coordinating a diverse array of professionals, administrators, and technicians alongside learners over a range of activities, times, and spaces—documents also become central, a glue that binds these people and their work together. Mehan's (2000) ethnographic study of the identification, classification, and labeling of educationally disabled children shows us the central role that documents can play in the coordination of educational interactions, decision making, and organizational work. His study draws on a range of methods; these include observing, interviewing, video-recording meetings, and lessons alongside asking teachers to reflect on the videos of these lessons. He uses the sequential paper trail that is created by a student (in class work, examinations, and educational testing sessions with the school psychologist) and created about a student (in their personal school records, school appraisal team committee, and eligibility and placement committee meetings) to focus the fieldwork on the range of sites where bureaucratic assessment and classification work occurs in the special-education referral process.

Documents, in the form of student records, are continually created and discussed by a range of professionals in multiple sites and spaces. Centrally, these records come to represent and stand-on-behalf of the student. In meetings about students, discussions routinely draw on and highlight aspects of the paper trail created by and about the student. The decisions that emerge from these meetings are central in classifying the child and, therefore, are central in creating their specific educational trajectory. In his study, Mehan (2000) does not present us with the documents themselves, rather he focuses on the distributed talk and actions of those people who create and use them. He shows us how the documents created by and about students become objectified and how the technical talk and decisions they facilitate are given much higher status than other forms of evidence such as a parental voice.

Ethnomethodological ethnography: documents-in-interactions

Research on documents within the tradition of ethnomethodological ethnography—and we include conversation analysis within this area—focuses on describing in great detail the moment-by-moment social organization of interactions with, around, and about documents (see Table 1, fourth column). Like ethnographic work outlined in the last section, it is not so much interested in the content of documents, but in the organization of interactions where documents take some role. However, in general terms, there are two central differences. First, for ethnomethodological work, the immediate, here-and-now, to-and-fro of the participants' interactions is the central object of interest, description, and analysis. Broader contextual factors, like participants' backgrounds or organizational policies, are generally not drawn on as a resource *a priori* to explain why an interaction happens in a specific way. Instead, the focus is on what the participants in the interaction show themselves to actually do, exploring the (contextual) resources they draw on in just that moment of interaction. Second, ethnomethodological work increasingly relies on audio or video recordings of naturally occurring interactions. These form the centerpiece of analysis, are subjected to repeated viewings, and sequences of interaction—including verbal and nonverbal features—are transcribed in very fine detail, analyzed, and revised in conjunction with the original recordings.

An example of this method in practice is Heap's various analyses of audiotapes of young children reading in classrooms (e.g., Heap, 1985, 1991). Rather than assuming we already know what reading looks like, or when it occurs in classrooms—through some *a priori* theory or criteria—he focuses on the broad range of interactional activities that produce the ongoing activity as reading. For him, children learn what counts as reading criterially, by learning what counts as reading procedurally, in and through taking part in interactions where "good" reading is shown to be taking place. For example, Freebody and Freiberg (2001) show how in a moment of a parent-child interaction, where a child is reading a book aloud, the parent works to praise, instruct the child to sound the letters, correct soundings, etc. In this moment of reading a document, the central interactional task is reading out loud a written text, and "good" reading is orientated to and produced as correct word-saying. In other contexts, say a university seminar on a specific article, through debating and discussing, students learn what "good" academic reading involves—finding fault, contrasting with other documents, quoting and referencing from this and other documents, reading footnotes, following up references, etc. Such work focuses researchers' attention on unpacking, in detail, how specific tasks are undertaken.

Documents are not only paper-based, single-user, objects and ethnomethodological ethnographic research has focused on how mundane and digital technologies shape the world of educational activities. Such research has focused on how people interact, work with, and draw on such document-related technologies as white- and blackboards, overheads, computer-based presentations, and videos. Rendle-Short's (2006) study of computer-science seminar presentations focuses on the academic monologue. She shows us how presenters work to interact with the audience not only through their talk, but also through their gestures, gaze, and bodily movements. Using a collection of videotapes of seminars and transcribing in great detail the moment-by-moment verbal and nonverbal behavior, she focuses on how presenters coordinate a range of documents and technologies as they seek to engage with the audience. As presenters talk, they time their slides to focus, support, and supplement the issues they are raising. The text-based and visual images on the slides work to illustrate some aspects of their ongoing talk, and presenters through their hand gestures work to direct the audiences' attention to a specific aspect or issue. In this way, we begin to see how, what appears as a relatively simple task—giving a seminar—is saturated with a complex range of interactional work. The documents the presenters

work with, be it notes available to them, or slides available to all, are brought to life and shaped through the concerted, moment-by-moment, organization of talk, gesture, and technology.

Such ethnomethodological ethnographic research findings can seem focused on the quite obvious, in that it can show us what we take for granted. However, researchers in this tradition argue that it is only through an understanding of the details of what we actually do (the details of which can largely escape our notice)—rather than what people tell us they do, or what we think they do—that we can then develop theories or interventions that are actually relevant to current practice.

Conclusion

Given the ubiquity of paper and digital documents in contemporary social and organizational life, the range of potential types of documents open to qualitative analysis is immense. However, the primary sources for educational research are policy documents (be they national, regional, or local), textbooks, and internal organizational documents; the secondary sources are from the academic canon. Documents in any broader sense—be they blogs, diaries, magazines, newspapers, or websites—are underused and underanalyzed. As noted above, the lack of focus on documents is not restricted to educational research but is instead endemic to the social sciences. On the one hand, this is quite surprising, given the centrality of documents to everyday experiences, the readiness-to-hand of document-based “raw data”, and that it does not have to require large amounts of time in the field collecting data. However, ideas around hearing peoples’ voices, witnessing things with your own eyes, have been increasingly positioned as a central requisite of authentic and high-quality qualitative research. Nevertheless, in relation to critical discourse analysis style studies of education, Rogers et al. (2005) see the turn away from a focus solely on written documents toward a focus on talk as a positive direction, in which new theoretical, methodological, and analytic possibilities emerge. Notwithstanding these potentials for development alongside the existing tradition of ethnographic work focusing on the use, role, and function of documents-in-action, we are still left with a relatively limited corpus of work that focuses on the social and educational lives of documents. Documents shape, and are reflexively shaped by, our perceptions, interactions, institutions, policies, and society. They are central in the production, reproduction, and transformation of our educational landscapes. As such, they deserve a more sustained and systematic analytic focus.

Introduction

As of 2020, the global Internet penetration mark has exceeded 50%; there are now more than 4 billion active users who use the Internet on a daily basis for an average of 6 h a day (We Are Social, 2020). In fact, every minute there are over 40,000 searches on Google, 527,760 photos shared on Snapchat, 4.1 million videos streamed on YouTube, half a million Tweets sent, and approximately 46,740 photos shared (Marr, 2018). Annually, the global population spends an astounding combined 1 billion years online. By region, the highest Internet penetration rates remain in Northern Europe at an average of 94% and the lowest Internet penetration rates are in Mid-Africa, at an average of 12% Internet penetration (We Are Social, 2020). Although there is much progress to be made to bring the remainder of the world's population online, with the rapid transformation of digital innovation in methods of Internet connectivity in the coming years (e.g., launching of satellites, solar balloons, 5G, etc.), more and more individuals from far flung corners of the globe will gain access to the Internet. Society is living through an exciting shift in how meaning is made and how individuals communicate, thus opening up a wide world of opportunities for researchers to understand how people make meaning of their world within, around, and through digital spaces.

Because of the influx and rapid shift in human communication methods—as evidenced in the aforementioned statistics—it is imperative that researchers and scholars develop qualitative approaches tailored to understanding meaning making and communication in online spaces. Scholarly research must begin to better understand the digital worlds that people inhabit in order to make sense of the diverse ways that people make meaning in and across online spaces. One such theoretical framework that accounts for the nature of interconnectedness in human and machine communication activities, and begins to delve into the multifarious ways that people make meaning in and across online spaces, is *networked field sites* (Gerber et al., 2017). Networked field sites are “dynamic spaces that are user-driven, social, and collaborative” (Gerber et al., 2017, p. xix). One of the defining features of networked field sites is that of connectivity and the way that data flow among, across, and between users, sites, systems, and services. A person might post something on his or her blog, perhaps a picture, image, or story. Another individual might then share or post that blog link on his or her Twitter, Tumblr, Instagram, or Facebook. Other individuals across the network might modify, change, adapt, or repurpose that post for his or her own purposes. The original post, now modified, might make it back to the original person in his or her blog community, therefore shifting and reshaping the original intent of the post, but having met the needs of larger group across the network. That same individual might later delete the original post, or perhaps the social media site might

delete the user account or post, therefore also solidifying the temporal nature of how information exists across the network, however, although the original might be deleted, the modifications to the original still remain intact across the larger community. This is the reality of the way that information exists within networked field sites. It is temporal, porous, shifting, user-driven, social, and collaborative and as such requires certain methodological considerations when bringing into any study.

This chapter will introduce readers to the ontological imperative framework, a methodological framework that is comprised of five sets of questions that walk researchers through a critical examination of the data that are yielded within online spaces. In particular, this chapter will introduce the framework and will provide an empirical example of the framework used within a qualitative study. The chapter will conclude with practical suggestions for the reader to consider in their own growth as a scholar and future research projects.

Digital methods in qualitative research in online spaces

Because networked field sites are dynamic, complex, nuanced, and porous, it is imperative to think through methods that will allow researchers to capture the meaning-making processes and experiences that people are engaged in when taking part in activities in online spaces. This warrants an understanding and development of new methodological approaches to study the way people interact in online spaces. As Gerber et al. (2017) posited, developing new methodological approaches to understand socialization and meaning making in online spaces "... will be warranted as technologies continue to permeate public and private spaces and as movement among digital and nondigital text continues to become routine" (Gerber et al., 2017, p. 168). Scholars have been quick to point out that traditional methods of research (e.g., interviews, surveys, etc.) might not support understanding how people and information move among, across, and through digital platforms and online spaces of the networked field sites and such researchers have been quick to call for the development of new methods that can capture and trace the ways that people make meaning in online spaces (Bruns and Burgess, 2013; Gerber and Lynch, 2017; Rogers, 2013). Traditional methods (e.g., surveys, interviews, observations, etc.) that have been ported to online spaces are known as *digitized methods* whereas new methods used to study online interactions are known as *born digital methods*, or *natively digital methods* (Rogers, 2013). These methods exist only because online technologies allow such methods to exist. Natively digital methods, such as web scraping/crawling, calling an application programming interface (API), and agent-based modeling emerged from fields of computer science and data science. Although typically used for quantitative analyses within data science (i.e., with big data), these methods are important to acknowledge for how they can inform a qualitative understanding of the meaning making among people occurring within networked field sites. Regarding the use of digital methods to study interactions in online spaces Rogers (2013) stated

Ultimately, I propose a research practice that learns from the methods of online devices, repurposes them, and seeks to ground claims about cultural change and societal conditions in web data, introducing the term "online groundedness." The overall aim is to rework methods for Internet-related research, developing a novel strand of study, digital methods (p. 19).

Digital methods, or those that are born out of the study of how online systems and digital objects themselves operate—such as recommender systems, hyperlinks, APIs, algorithms—can provide a unique understanding of how to redesign and develop new methods for the study of meaning making, socialization, and culture in online spaces, including the networked field sites that a researcher might be engaged in studying. Simply taking traditional methods such as interviews, surveys, and observations and relying upon those methods as the sole methods to study online spaces means that a scholar has not acknowledged the operational facets of the networked field site that he or she is researching. A networked field site operates on binary code, is powered by algorithms, and driven by software. Acknowledging that the field site itself is unique, because of the networked system within which it operates, provides researchers a solid footing for engaging in a critical deconstruction of the very sites, spaces, systems, services, and people that they are studying.

Lynch and Gerber (2018) created a *methodological* framework, termed the *ontological imperative*, for researchers interested in studying back-end metadata (e.g., social media metadata, such as Twitter metadata) born out of networked field sites. The ontological imperative framework poses five sets of questions that allow the researcher to critically examine their data, in essence serving as a who, what, when, where, and why. The five sets of questions require the researcher to fully explore the strengths and weaknesses of their data so that any epistemological claims that they make can be grounded in truly understanding their data. Although originally the ontological imperative framework was developed to guide researchers as they delve into the black box of algorithms and social media metadata in mixed methods studies, the framework can be used to shape and frame qualitative research that includes networked field sites, primarily because qualitative studies take place in networked field sites that include online spaces, actors, and participants that are temporal, transitory, and porous. This temporal, transitory, and porous nature of all online spaces requires the same level of examination by researchers doing qualitative research as with scholars conducting mixed methods studies that employ social media metadata. Of particular note, the ontological imperative framework requires researchers to provide readers with a level of transparency for their research and their data. The following sections will outline and demonstrate uses of the ontological imperative within networked field sites.

Technical outline of the ontological imperative in web-based qualitative research methods

The ontological imperative framework is guided by five sets of questions that allow researchers to examine the data collected from the digital tools, systems, and services in their studies. These questions, when used as a methodological framework, provide context for the researcher's findings. Because the philosophical roots of ontology are concerned with the nature of being, it is important to engage in understanding the very nature of what it means *to be digital*. In the case of research that occurs within digital spaces and networked field sites, the very nature of what it means to be digital and networked, given the temporal, ephemeral, transitory, and porous nature of the digital and networked, must be examined at every level of a study. The five sets of guiding questions of the framework are as follows:

1. What digital tools, systems, and services are at play in my study? Who created them and why?
2. What data do these digital tools, systems, and services render?
3. What hidden limitations might there be to the data rendered via these digital tools, systems, and services?
4. What are the epistemological implications of this ontological analysis?
5. What are the axiological implications of this ontological analysis?

Question 1: what digital tools, systems, and services are at play in my study? Who created them and why?

This question delves into the nature that all digital technologies come laden with biases, purposes, and motivations of specific individuals who created them as well as those who are using them. This question provides a framing for researchers to critique and question the purposes behind tools, systems, and services that are part of the networked field site that are part of a study.

Question 2: what data do these digital tools, systems, and services render?

This question forces researchers to think about what sort of data are created and available within the networked field site under study. How much of the data are rendered by humans (e.g., text, chat, images) and how much of the data are rendered by machines (e.g., governed by an algorithm or system design). This question also forces researchers to contend with what data might not be made available by the system and to challenge why this is so and whether the data that they are able to collect is useful for the questions that they are asking.

Question 3: what hidden limitations might there be to the data rendered via these digital tools, systems, and services?

This question forces researchers to contend with what data might not be made available by the system and to challenge why and whether the data that they are able to collect is useful for the questions that they are asking. Furthermore, this question asks researchers to consider shifts in data and space use over time and in temporal contexts. Because digital tools, systems, and services are in a constant state of flux, one must continuously examine the shifts and changes in their data corpus. In networked field sites and online spaces, data are always incomplete. Companies choose which data to make available, which parts of the system can be accessed by the public, as well as how the online spaces, actors, and data can be accessed and by whom. This question forces researchers to think through what data might not be available and to challenge their own pre-conceived notions about shortcomings of their current data from both current and historical uses of the tools, systems, and services.

Question 4: what are the epistemological implications of this ontological analysis?

This question provides space for researchers to account for what they have come to learn and know about the very nature of the digital tools, systems, and services in their study in order to ensure validity and trustworthiness of their findings. It challenges researchers to make connections among the previous three questions and to consider if other questions, data, or purposes should be considered for the study.

Question 5: what are the axiological implications of this ontological analysis?

This question requires that the researcher consider the ethical concerns brought forward by the analysis of the aforementioned questions regarding the digital tools, systems, and services. What levels of concealment are needed to protect participants whose data were collected from within often public digital spaces and forums? Are levels of concealment on easily searchable names, places, sites, and spaces needed? What might be missing from the analysis that might need more careful consideration?

Empirical demonstration of ontological imperative in web-based qualitative research methods

This next section will walk through applying the five sets of questions from the ontological imperative framework to data from a 5-year ethnographic investigation that I have conducted of the networked field site of a competitive collegiate Esports team (Gerber, 2022). Esports, short for electronic sports, is competitive, team-based videogaming that takes place across multiple levels—from amateur to professional. In particular, for over 5 years the purpose of my research has been engaged in studying the literacies, epistemologies, and meaning-making practices experienced by individuals engaged in the culture of collegiate Esports. This research has required me to trace meaning-making experiences across and through both analog and digital spaces, including using traditional methods (e.g., interviews and observations), as well as natively digital methods (e.g., calling an API). In the remainder of the chapter I will walk through applying the ontological imperative framework to the digital tools, systems, and services within my study.

Question 1: what digital tools, systems, and services are at play in my study? Who created them and why?

In order to study the literacies of competitive collegiate Esports, I had to become familiar with the main tools, systems, and services used by my participants. The main digital tools, systems, and services that were used in my data corpus came from *League of Legends*, Twitter, and Discord. For the purposes of considerations of space in this chapter, I will focus the ontological imperative only on an analysis on *League of Legends*.

League of Legends is a multiplayer online battle arena (MOBA) developed and published by videogame company Riot and was released to the public in October 2009. *League of Legends* is a MOBA-style videogame (Multiplayer Online Battle Arena), which in particular, MOBAs are created for the purpose of television broadcasting of competitions. The game is often played with teams of five players versus other teams of five players, known as a 5v5 match. Players can join the game either by entering a waiting arena for matchmaking and allowing the system to assign them to ranked matchmaking or they can play on pre-selected teams of five. Players each have their own avatar, known as a champion, that is equipped with certain skills, traits, and attributes. Because of this character selection, each person plays a specific role, much like a traditional sport, such as basketball or football where players play a specific part of the field or court with specific rules for their position. On the financial side, Riot is a for-profit company and the game uses a freemium model, which means that although the game is free to play, there are items for purchase by players for specific upgrades, items, or features to enhance their character's abilities.

Question 2: what data do these digital tools, systems, and services render?

At the surface, the user interface of the game provides in-game statistics such as leaderboards listing kills, deaths, assists. It provides markers of in-the-moment in-game play such as progress bars that show amount of health left, amount of mana (magical power for casting spells), menu of items (e.g., swords, spells, potions, etc.) that can be equipped by the player at any moment in time in the game if needed, as well as charts of statistics that show amount of time lapsed, time to respawn, and icons for each of their team mates that provides details on status of the team mate. Additionally, there is a map that allows a player to see where other team mates and opponents are at any given time in a match. Lastly, there is a chat window that serves as a channel for team mates to discuss in-game strategy as they play. By examining the features that are viewable on the surface, it is apparent that there are a plethora of data to be collected. See Fig. 1. This first level of analysis to know what data someone might encounter in a digital space is known as surfacing the data (Gerber and Lynch, 2017).

The next level of analysis that a researcher must do, before fully determining what data will be helpful to paint a robust picture, is to delve into the back end of the digital tool, system, or service. Although this might seem to be a complex activity that requires a researcher to be a programmer, developer, or a computer scientist, the activity of looking to see what backend data are currently is available is actually easier than it might first appear. Generally, companies have a repository that lists what data that they are making available to developers via the API. This is known as Developer Documentation and nearly every digital space that allows transfer of information between competing sites and apps has Developer Documentation on their website. In the case of my research that included *League of Legends*, this was located on a page titled "League of Legends Developers Portal." A deep dive into the developer documentation in December of 2020 showed 22 specific API Keys, which each key allows an individual to procure specific data about specific access points of the game. For example, there is an API Key that is Titled "Account-V1" that allows an individual to access specific backend metadata about user accounts including backend data about user ID. Another specific API Key is titled "Tournament-V4" which allows an individual to access tournament codes, lobby events, and player specific data for these events. To understand which categories are important for a researcher to examine, it should be noted that the terminology used in API calls such as "Get," "Post," and "Put" are all related to the methods used in API communications. A researcher looking to retrieve data from a site should focus on the categories of the API Key titled "Get" versus "Post" or "Put." Figs. 2–4 show examples of the deep dive into the *League of Legends* Developer documentation.

Although the aforementioned walk-through might appear a bit cumbersome, it is important to note what data are available to developers and individuals. These data can often be accessed by researchers via their own API calls, providing insight into different ways to ask research questions about the participants under study or to think about different data that might be available to help answer a question. A researcher might not know how to program, but can often work with a computer programmer (e.g., a student,

Fig. 1 Screenshot of data surfacing activity of league of legends

Note: This figure shows the various types of data available *on the surface*, when doing an analysis of League of Legends in-game screen. Various data points include in-game chat, status bars, in-game map, in-game statistics, team mate information, and available in-game equipment, potions, and weaponry.

faculty member, etc.) to conduct the API calls. Even if the researcher determines that they do not want to do the API call, it is powerful to know what data are being made available by the company, as this can lead to new insights about how to ask research questions based on data that the researcher might not even know is available (such as geolocations, time stamps, user metadata related to user networks, etc.).

Question 3: what hidden limitations might there be to the data rendered via these digital tools, systems, and services?

Question 2 of the framework encouraged researchers to engage in data surfacing and backend mining to understand what data were being made available. As noted, doing this sort of investigative work will allow a researcher to refine research questions, delve into data structures, and better understand how to study interactions with the tool, system, or service. However, as discussed previously, digital spaces are temporal, porous, and transitory. This means that what is available today might not be available tomorrow. Additionally, it should be noted that companies are not going to make available all of their data to developers or researchers. What one sees when they visit a company's Developer Documentation is only a partial glimpse into the data that are being collected from individuals who use that tool, system, or service.

Fig. 2 API keys

Note: This figure shows a list of available API Keys on the left-hand side (note that the list is longer than shown), with three specific calls for that API key located in the middle of the Figure, as noted by the "Get" block. To the right of the "Get" block is the specific key followed by the far right which explains what sort of input criteria is needed to pull that information from the back end of the site.

There are three routing values for account-v1: americas, asia, and europe. You can query for any account in any region. We recommend using the nearest cluster.

Fig. 3 Specific API key information

Note: This figure outlines the specific API call to get the backend data about specific accounts via the Riot ID.

As scholars, unless we work for the company for which we are studying, there is no way to know what other data are being collected, however, it is important to account for the fact that indeed other data might help to better answer that question and to think about what data a researcher would like to see, either on the surface via the user interface or on the back end. This type of critical questioning can help the researcher with the refinement of research questions. However, for purposes of transparency in the research process, when examining the available data (either through front-end surfacing or backend mining), it is important to note the temporal and transitory nature of data. As mentioned prior, the data that one collects today might not be available tomorrow, and it is important to track and trace shifts in data across time to understand the epistemological implications of one's research. The simplest way to understand how companies shift their access to data, or changes in types of data made or available or user interface structure is to think through the historical traces of the tool, system, or service and to use the Internet Wayback Machine (circa 2001) to do so.

The Internet Wayback Machine is an archive of most webpages dating back to 2001. As of this writing, the Wayback Machine has archived over 486 billion webpages. The Wayback Machine routinely crawls the Internet (using a web crawler) and archives and caches websites at specific intervals. This allows an individual to revisit an older version of a website to see what information was available at a key date in time. It is a useful tool for a researcher engaged in scholarship in networked field sites because it allows a researcher to note potential changes to available data, which might directly, or indirectly, influence how one arrived at his or her epistemological claims.

In order to understand my data on *League of Legends*, given that my study spanned 5 years, and to question shifts in my own participants' behaviors and literacy practices, I needed to examine some of the differences that have emerged on the site and in

The tournament-stub API is a stand in that simulates the behavior of the tournament API. Developers looking to apply for tournament API access should use the stub to mock their implementation before applying for a production key.

the game over time. Using the Wayback Machine, I was able to access archived pages dating back to mid-2011 (see Fig. 5). Given that my study started in mid-2016, this year was the most relevant to start with for historical analysis. Historical access provided insight and reminder into parts of the game and community that are now defunct, such as access to the Tribunals, a community-driven system of removing toxic players from the game and access to developer documentation showing changes to API access and API data points.

Question 4: what are the epistemological implications of this ontological analysis?

A thorough analysis of the digital tools, systems, and services that were a part of a study allowed a deeper understanding of the production of data and the available data sources available. Question 4 of the framework is concerned with ensuring that researchers account for the nature of the digital data, products, or services that they use in their study in order to better support their epistemological claims. Primarily, this accounting allows for replicability of the study among other scholars. Replicability is the bastion of academic rigor, and although it is argued that qualitative inquiry is more difficult to replicate, if a researcher accounts for the processes of data procurement in digital tools, systems, and services, this provides a transparent audit trail for other scholars who wish to replicate the study.

In the case of my analysis of *League of Legends*, when examining the first three questions of the framework I developed a deeper understanding into the structure of the online space/networked field site (e.g., a for-profit company) which in turn influences the types of data made available for me as a researcher. This analysis allowed me to examine through front-end surfacing, back-end mining, and historical and chronological overview, insight into how my participants came to engage in the meaning-making processes and literacies practices within the *League of Legends* system. Understanding game updates, patches, and site upgrades,

Fig. 5 Historical snapshot of the Internet Wayback Machine for league of legends

Note: This figure shows the historical archive of the *League of Legends* website dating back to 2011. The bubbles on each date are directly proportionate to how many snapshots, or archived crawls were captured on a given date.

which are all traceable through the aforementioned methods, allowed me to dig deeper into understanding the data that I had collected in order to trace the way that information has flowed among and between players and to in turn, reframe my research purpose as well as re-examine the types of data that I thought I originally needed to answer my research questions (e.g., looking at different metrics of in-game success as well as branching into different online social spaces and networked field sites, such as Discord).

The changes that have occurred in site design and purpose (i.e., the loss of the Tribunal space), the changes in the types of data visible on the surface and user interface, and/or the types of data made available in the back end via the API over time, all influenced the epistemological claims that I, as a researcher in this networked field site, was making. Accounting for these changes and shifts provided an audit trail for me to reflexively visit, which provided a more robust framing for the study's trustworthiness, which allowed me to more confidently state claims and posit implications about my study's findings.

Question 5: what are the axiological implications of this ontological analysis?

Although axiology deals with value, the focus of axiology in the ontological imperative is concerned primarily with ethics. Understanding the ethical implications of research that occurs within a networked field site is crucial. Whenever a researcher enters an online space or uses digital tools, systems, or services, with the main mission to study participants within the space, the researcher risks divulging sensitive participant information if due caution is not exercised.

For example, API data (e.g., back end system data) are generally considered public and scholars have argued that researchers should be able to freely use these data to help inform their studies (Manovich, 2012). However, data that at one point might be considered private data under password protection, might become publicly available if the company changes the Terms of Service or if the company is acquired by another company (Gerber et al., 2017). Because of this, researchers should think through ethical considerations as they engage in their ontological imperative analysis. Even if participants have signed informed consent, it is imperative that the researcher consider future harm that their research might have if data shifts, if acquisitions occur, and if Terms of Service changes make that data public. Guiding questions such as,

- To what extent is these data collection and analysis ethical?
- Do the Terms of Service allow for this use of the space and data collection from the space?
- What harm could these findings have on my participants if any of specifics of the study were suddenly made publicly available?

In order to mitigate risks, with my study of *League of Legends*, once I completed the ontological imperative analysis, I engaged in Bruckman's (2002) levels of concealment (see also Gerber et al., 2017). In particular, once I engaged in historical analysis through the Wayback Machine, when paired with my front-end surfacing, and back-end data mining, I determined the most appropriate level of concealment would be to engage in not just use of pseudonyms, but renaming any @mention, paraphrasing direct quotes from any game chat or messaging system, and concealing or changing specific mentions to sites or locations. Ensuring transparency in the methods used (i.e., by providing a walkthrough of the ontological imperative), as well as concealment of the actual data (i.e., by using levels of concealment of sensitive participant data), provided a deeper ethical treatment and consideration of my participants' data than simply reporting the data in its initial form and hoping that shifts in Terms of Service or data availability would not change in the future. These ethical considerations are crucial for all researchers who engage in research within networked field sites.

Ways to continue growing as a researcher in web-based qualitative research methods

The very nature of conducting research of networked field sites using the ontological imperative framework requires researchers to change the way that they think about research in online spaces and subsequently how they approach their research. Beyond simply accounting for the ontological imperative in the methods section of one's article, dissertation, or manuscript is acknowledging that one should be continuously learning about new methods of scholarship and inquiry. The following concrete examples offer suggestions for how researchers can continue to grow as scholars doing qualitative inquiry in online spaces and networked field sites.

Read up on digital methods and theories of interaction in digital spaces

Researchers interested in continuing to learn about qualitative research methods in online spaces should begin by digging into theories proposed in the arena of software studies and digital methods. Software studies provides a foundational theory for understanding networked field sites and research in online spaces. Furthermore, researchers interested in furthering their understanding of *digital methods* (e.g., natively digital, such as web crawling or API calls) versus *digitized* (e.g., online surveys) should invest in reading about digital methods. The following four books provide a primer into software studies and digital methods.

The first book, *Code/Space: Software and Everyday Life* (2011) by Rob Kitchin and Martin Dodge provides an overview of how software and computer code permeate every aspect of our lives, from the way that we grocery shop to how we decide where to go on vacation. Their text is part treatise and part manifesto for understanding how our lives are governed by software and what we can do to understand the social, economic, and political implications of living within a software space. Second, *Software Theory: A Cultural and Philosophical Study* (2015) by Federica Frabetti deconstructs software and code to show that at the center of the software that powers our lives, and central to the code that dominates software, are human languages. Software, and at its very base,

code, is indeed an incredibly human creation governed by rules of language, syntax, and grammar. These same rules are therefore then enacted with human biases and limitations. The third text, *Digital Methods* (2013) by Richard Rogers is a fantastic primer on the various digital methods available to researchers. Offering a historical overview of a variety of approaches such as web-crawling and API calls, Rogers noted "... [digital methods] seek to ground claims about cultural change and societal conditions in web data" (2013, p. 19). Finally, *Quantitative Ethnography* (2017) by David Williamson Shaffer is a must read that explores the qualitative approach of ethnography and pairs the approach with Big Data.

Conduct software and app walkthroughs

One activity that can help a researcher better understand the tools, services, and systems of a networked field site is to engage in a software or app walkthrough. A walkthrough is a process that allows a researcher to develop new eyes for the digital tools, services, systems, and spaces that he or she is studying. The process should progress from onboarding all the way through exit or leaving a system.

To do a thorough walkthrough, a researcher should ensure that they have screen capture software ready and that they are logged out of the tool, system, service, or space. This process requires that the researcher set up a new account for whatever tool, system, service, or space that they are studying in order to give them fresh eyes and a new perspective as they walk through the app or program. The researcher should document and annotate the entire process for later review. The process starts with the onboarding into the tool, system, or service which includes signing up for an account. As the researcher signs up for an account he or she should screen capture, annotate, and document what he or she is noticing, including issues, and/or ideas that he or she has about the user interface. Walking through the entire platform, the researcher should document and annotate the entire process. This walkthrough will help spark ideas for areas of later exploration and/or deeper understanding of the user interface and its impact on a study's participants.

Explore developer documentation for different spaces

Similar to the software and app walkthrough, researchers should also engage in exploring the developer documentation of any of the tools, systems, and services that are part of the networked field site that they are studying. By digging into the developer documentation, a researcher can develop a better understanding for what data are available, which can help to shape potential research questions and/or influence the research purpose. Similar to the software and app walkthrough, researchers should be documenting and annotating findings and insights, either via screen capture or recording software. These annotations can become part of later reflexive journaling and audit trails.

Connect with colleagues interested in research in digital spaces

As scholars engage in learning about conducting qualitative research in online spaces, it is important to join communities of researchers and scholars who are also engaged in learning about and developing new methods for studying online spaces. There are several existing organizations and/or groups focused on the study of methods for researching online spaces. The Association of Internet Researchers (AoIR), founded in 1999, is an international organization made up of researchers from across multiple disciplines who are dedicated to the critical and scholarly study of the Internet. AoIR hosts an annual conference as well as regular webinars and produces academic material and guides to aid scholars in their design of studies—both novice and experienced. For more information visit <https://aoir.org/>. Another organization, the Digital Methods Initiative (DMI), is based out of Amsterdam. DMI has created over 50 web-based applications and pre-built tools for working with back-end metadata from a variety of digital tools, systems, and services such as Google, Facebook, Twitter, Instagram, Amazon, etc. Furthermore, DMI hosts two events a year aimed at teaching people how to conduct research using digital methods. For more information visit <https://wiki.digitalmethods.net/Dmi/DmiAbout>.

Final thoughts

In developing new methods and approaches to studying online spaces, it is important that researchers concerned with studying networked field sites should strive for *the radical middle* (Onwuegbuzie, 2012).

... which should not be as passive and comfortable middle space wherein the status quo among quantitative and qualitative epistemologies is maintained, but rather a new theoretical and methodological space in which a socially just and productive co-existence among all research traditions is actively promoted, and in which mixed research is consciously local, dynamic, interactive, situated, contingent, fluid, strategic, and generative (p. 192).

Developing new methodological approaches for use within networked field sites, particularly when framed through the radical middle, means researchers must critically question every nuance and aspect of the online spaces that they and their participants

inhabit. This includes considering the flow of information and the fact that information is not static in these spaces, understanding that there is a middle ground between the online space of the physical and the digital that allow for the creation of that networked field site. This is the radical middle in studies that take place in online spaces. Although Onwuegbuzie's theory of the radical middle is primarily concerned with mixed methods research, we can learn a lot from how the radical middle can influence our understanding of qualitative approaches in online spaces. Learning to adopt new methods and approaches to understand interactions in online spaces is beyond simply adapting existing qualitative approaches. The radical middle philosophy provides a framing for why the ontological imperative is such a crucial framework for scholars to consider when conducting qualitative research in online spaces and networked field sites. Scholars must adopt a stance and frame of mind that allows them to interrogate the very tools, systems, and services in their study to look for inherent biases and limitations in the data and to expose these biases and limitations in order to ensure transparent scholarship that is not only replicable, but opens up a venue and space where research is subsequently, "... consciously local, dynamic, interactive, situated, contingent, fluid, strategic, and generative" (Onwuegbuzie, 2012, p. 192). Only then, once a researcher has completed an ontological imperative analysis, can a researcher's epistemological claims hold weight.

Introduction

Qualitative analysis—the interpretive analysis of textual, graphical, or audio/video data—occupies a continuum from description to theory building, from addressing *what* questions to attempting to answer complex *how* and *why* inquiries. Though researchers might discuss analysis as a phase, it is best to anticipate analytic strategies even during design and data collection. For example, if we are interested in lived experience, discussed later in this chapter, we need to generate data that provide access to the nuanced texture of an experience as it is being lived. But we would also benefit from developing an analytic perspective as we collect data so that we can begin examining data as we collect them, such as writing memos on especially meaningful text segments.

Qualitative studies can be directed by a conceptual framework, suggesting a deductive thrust, or driven more by the data itself, inviting an exploratory, inductive lens. In either case, the topics we wrestle with can range from tangible to abstract. How we engage these topics varies dramatically based on our strategies for analysis. A descriptive study might identify and illustrate barriers and facilitators of a public health intervention whereas an inductive thematic study would raise topics, or combinations of topics, to a higher conceptual level. Theme-building allows researchers to make interpretive claims by weaving together evidence across data and data types and naming these dynamic links. A theoretical study would go even further to make explanatory claims based on evidence across data and data types, attempting to theorize relationships between individuals, structures, and processes and not simply describe a situation, event, or experience.

In addition to presenting thematic analysis as a strategy, this chapter also covers established qualitative traditions: case study, ethnography, grounded theory, narrative analysis, and phenomenology. Case study research involves identifying a bounded “case” and collecting multiple types of data to assess the case and its context, either descriptively or more thematically. Ethnographic research focuses on a cultural setting and uses rich description to understand how individuals participate in the same culture, perhaps in markedly different ways. Grounded theory encompasses several approaches, including objectivist and constructivist, that invite researchers to analyze process, contexts, structures, and consequences. Narrative analysis treats stories not only as possible representations of events, but as narrative events in themselves. Researchers using this approach analyze the form and content of narrative data and examine how these elements serve the storyteller and how the story shapes ontologies and epistemologies. Phenomenology is an approach designed to “open up” a phenomenon and make sense of its invariant structures, its identifiable essences across narrative accounts. In this approach, the focus is on the lived experiences of those deeply familiar with the phenomenon. Each of these traditions has its own investigative emphases and particular tools for analysis—specific approaches to coding and memo writing—and conventions for final products, such as diagrams, matrices, and condensed reports.

Overview of analytic practices and strategies

This section focuses on particular analytic practices—coding and memo writing—as well as a common analytic strategy, inductive thematic analysis. How analytic practices are adopted depends on the conceptual “compass” a researcher might bring to a study. There are numerous compasses or possible points of departure, depending on the current knowledge in the field as well as the particular focus of inquiry. The point of departure is the combined knowledge and objectives that guide the initial phase of inquiry.

There may be little established knowledge in an exploratory study or an extensive body of research that already speaks to a research question.

Researchers using a deductive approach might make use of an existing theoretical framework, such as activity theory, which sees activity as purposeful and transformative, or they might construct a conceptual framework based on a directed literature review. Particular fields, such as implementation science, offer specific guidance in the form of previously existing codebooks, such as the consolidated framework for implementation research (CFIR) (Damschroder et al., 2009), a collection of constructs reflecting the uptake of research findings into routine healthcare. When a theory or a conceptual framework is present in inquiry, these frameworks become a compass of sorts guiding the analysis. Researchers may then illustrate how their data align with or problematize the theory or conceptual scaffolding with which they began.

In the absence of a theoretical or conceptual framework, researchers are guided by a more data-driven approach, where the language of the data and the way that participants frame events, structures, and outcomes become topics that guide the analysis (Maietta et al., 2018; Saldaña, 2021). Though this approach might be considered more “exploratory,” it is not an unmoored one. Exploration is governed by research questions, by disciplinary understanding, and by a particular paradigmatic lens. For this reason, documenting one’s point of departure is imperative. It gives a researcher space to acknowledge how prior knowledge can be both a strength and a drawback. A researcher may need to “un-know” and un-learn what they have already learned in order to gain insight into the individuals’ experiential framing (Vagle, 2018). In an inductive approach, researchers experience the shifting sands of emergent ideas and build scaffolding for the study as they go. Entering the “unknown” privileges participant knowledge rather than relying on researcher knowledge or cumulative understanding based on pre-existing frameworks.

Reading textual data with an interpretive lens is itself a skill requiring an eye for nuance as well as holistic contiguity. In acknowledging the contiguity of an interview or focus group, we see how a participant or group has created a holistic account even if our questions were not attempting to generate holism. Attending to the participants’ framing can help us understand their complex experiences, governing values, or psychological landscape. For example, a participant who references religious beliefs throughout an interview even when the questions are not about religion can help us understand how a religion meaning system permeates their everyday experiences. In inhabiting data, we are invited not to be critical of participants but to understand events as they understand them—to analyze, not necessarily psycho-analyze—to consider the narrative territory of the interview in terms of ideas such as primacy (what comes first in a narrative), negation (negative language), emphasis (text treated with heightened regard), and repetition (repeated phrases) (Alexander, 1988). A narrative landscape, like a literal landscape, has different terrains, transitions, and elevations. We might notice places where participants center particular values, decenter other values, or demonstrate negotiated values (Daiute, 2014), such as librarians who are asked to catalog a title using categories that they find problematic because of their racist overtones. Prompts for attentive reading include: What is at stake here for the participant? What does the participant reveal beyond the “facts” of an incident? How does their way of speaking or constructing an account differ from how other participants in the study share their experiential accounts?

Coding practices

Many researchers have discussed possible coding practices for qualitative research (Charmaz, 2014; Miles et al., 2020; Saldaña, 2021; Strauss and Corbin, 2008). Codes are a vehicle for paying attention, a way for researchers to help establish consistency as they review and name pieces of data. If used intentionally and strategically, coding is a way of knowing and making meaning of copious amounts of data. In some studies, codes can be developed even before data collection, as would be the case if using the consolidated framework for implementation research (CFIR). Even without a framework, researchers might nonetheless develop an initial codebook based on the research questions, interview questions, and study aims.

In contrast to deductive coding, inductive coding is based on discerning and naming “surfacing” topics in close reading. For example, in vivo coding uses the participant’s own language to name a topic. In this practice, a concisely expressed belief, such as “life is empty without family,” becomes the name of the code itself, rather than introducing the researcher’s academic language that may lose the intensity of the quoted text. Another inductive coding practice, process coding, uses gerunds, or “ing” nouns, to capture actions and behaviors evident in the data (Charmaz, 2014; Saldaña, 2021). This practice helps researchers move closer to the participant experience—what they are doing or going through—rather than focusing on nominalizations that may ignore process. This coding technique can ultimately help us study what keeps a behavior or action in place, what reinforces it, and what destabilizes it.

We might also make a distinction between descriptive and interpretive coding. In descriptive coding, we take inventory of the tangible *who*, *what*, *where*, and *when* of data—emotions, settings, relationships, and timespans. However, focusing on description may result in a flat analysis without generating deeper insight. Interpretive coding, in its more conceptual nature, invites us to distinguish the implications and underlying meaning of what is being stated, moving closer to addressing *why* and *how*, but also reconceptualizing the *who*, *what*, *where*, and *when* in conceptual terms. So, we might rethink the codes *teachers* and *parents* in terms of *role models* or *dream makers*. Likewise, instead of coding for *frustration*, we might code for *managing emotions*, a more interpretive code that gets at an underlying process, a more meaningful topic with analytic leverage across transcripts.

Coding is an analytic act, but not a destination. Once we have coded data, more interpretive labor lies ahead in assessing what is “inside,” “outside,” and “in between” the codes. Assessing what is “inside” a code refers to evaluating the text segments contained within it to assess the data cumulatively regarding the spectrum of voices within, and properties of, the code. For example, we might find a range in the magnitude of the code, from low to high intensity. We might similarly assess what lies “outside” the code, that is,

what contextualizes or frames it. For example, we might discern that *managing emotions* is often coded within a particular time period or event, such as *turning points* in a career trajectory, contextualizing conflicting emotions within temporal markers. Finally, in investigating what happens “between” codes, we might see that two codes reveal more together than they do separately. For example, we might discern that *home life*, when assessed alongside *work life*, provides insight into a new concept, *actual self vs. ideal self*. These examples are reminders that though codes may seem like self-contained ideas, they become building blocks for further analytic inquiry when we look at the dynamic relationships between them (and contextualize codes within enveloping ones). We find other stories to tell and higher-level concepts that bridge seemingly unrelated topics (Maietta et al., 2021).

Memo-writing practices

Qualitative data collection can generate overwhelming amounts of textual data that require reliable practices to help us condense and synthesize our understanding. Coding is a practice that helps us consolidate this text into more manageable units and topics. Memo writing, in parallel, is another practice that can help us formally monitor and develop our evolving ideas as we move across data. The two practices differ in that codes tend to track individual, separable topics whereas memos function as a place to sustain complex inquiry, a space to draw connections between quotations, documents, or codes.

Types of memos include a *document reflection memo*, which treats an interview or other transcribed encounter as a contiguous whole that reveals consistent threads regarding values, beliefs, and attitudes or, of equal interest, contradictory threads regarding these topics (Mihás, 2022). Though we might have asked targeted questions in a structured or semi-structured interview guide, the landscape of an entire interview can help us understand the big picture, and as a result, we might become more aware of chronological trajectories, belief systems, or psychological states that take shape during an interview, insights we might otherwise miss in focusing solely on textual fragments.

In addition to coding text segments, *memos on key quotations* can help us better understand illustrative pieces of data. A key quotation is a text segment that is especially informative in that it reveals a way of thinking, behaving, or experiencing a phenomenon. When an opioid user says, “every ‘never’ I ever said came true,” we might pause to open up these words and explore what they mean for the participant and the larger research inquiry (Mars et al., 2014). This kind of reflective memo allows us to elaborate on what participant language is teaching us and how it helps provide insight into the intricate insider perspective. The content of these memos can also be used to develop codes.

Cross-document *comparison memos* move beyond document-level or segment-level quotations to synthesize meaning across data. By creating an intentional space to compare a particular topic—an experience, belief, or value—and its dimensions, this memo serves as a place of growing insight that also functions as pre-writing for a more formal paper or report. That is, when we have a hunch in one interview, we might intentionally write about it and refine the memo, and our proposition, as we review more data. In looking at the experiences of US parents whose children were soldiers in Iraq during the early years of the Iraq War (2003–2011), a comparison memo might show, for example, that mothers inhabit a limbo state of “what-if” thinking versus news of actual events (Collins, 2008).

Coding itself can also help us compare a topic across data, but it is sometimes difficult to code for an idea that permeates an entire transcript or to code for what is happening “between” text segments, that is, to code for the subtextual “rhyming” that happens when one segment is juxtaposed against another. A comparison memo can help us keep track of these slippery concepts that require elaboration as we find examples that offer complementary or contradictory perspectives.

Invariably, most qualitative findings show up as written claims. Memo writing as a practice can help us develop a writing voice that is congruent with our data and a way to interrogate evidence for a claim. In speaking with, not for, participants and braiding our voices with participant voices, we are more likely to stay close to the data and present co-constructed insights that serve both academic journals and communities from which the voices arose. For this reason, engaging in memos throughout the entire research lifecycle can help us invest in writing as a “way of knowing” (Richardson, 2000). This makes the task of final reports and papers more efficient because we have already developed the textured language of the study, rather than reducing writing to “write-up.”

Inductive thematic analysis

Thematic analysis, which can include both deductive and inductive practices, was developed across disciplines throughout the twentieth century, including work in physics by Gerald Holton (1973). In more recent years, psychologists Braun and Clarke (2006) outlined a set of theme-building procedure for the social sciences, but thematic analysis remains a loosely defined practice with many varied applications across fields of study and across a “range of theoretical and epistemological approaches,” such as case study and ethnography (Braun and Clarke, 2006, p. 6). Though some researchers argue that thematic analysis is a method in its own right, others, such as Morse and Cheek (2021) and Boyatzis (1998), consider thematic analysis a practice or a tool. As such, thematic analysis is not exclusively tied to a particular epistemology or paradigm. If we adopt a realist paradigm to assess the barriers of emergency medicine, we might construct themes that elucidate treatment barriers. If we instead adopt a constructivist paradigm, we might develop themes to capture social structures evident in an emergency setting, such as how built environment “acts” upon patients.

Though deductive approaches to thematic analysis, such as directed content analysis, are common (Bingham and Witkowsky, 2022; Hsieh and Shannon, 2005; Mayring, 2015), they are beyond the scope of this chapter. Instead, this section focuses on *inductive*

thematic analysis, whereby researchers do not begin with theoretical constructs or frameworks. They start only with provisional topics that work their way into an evolving codebook. During the initial review of data, called “open coding” or first-cycle coding, researchers generate numerous topics, both broad and specific (Charmaz, 2014; Saldaña, 2021). Open coding, often descriptive, invests in the language of the participant as well as the aims of the study. However, thematic analysis does not stay at the level of description or initial insight. Researchers move up the conceptual ladder from this vast array of ideas to develop conceptual clusters using evocative, condensed language.

Codes and themes occupy different semantic planes. A code is a container for a single topic, whereas a theme goes further in capturing dimension or meaning across multiple codes and in this way acts as an “argument” about the “phenomenon being examined” (Braun and Clark, 2006, p. 18). For this reason, topics such as *barriers* and *facilitators* are regarded as broad topics that do not adequately elevate ideas to a more compelling claim or theme, which tends to be more evocative, such as the *family obligations intensify transportation barriers*. In other words, themes pierce the surface of data to evoke a higher-level story or abstract concept. They go deeper in unearthing participants’ tacit assumptions and pervasive logics and in connecting seemingly different topics, such as family and transportation in the above example, and naming this dynamic link.

There is no single agreed upon strategy for determining themes, but researchers might create clusters of seemingly related codes and then name the conceptual glue that holds them together. Hence, in a study on experiencing chemotherapy, descriptive codes for *eating new foods*, *seeking new entertainment*, and *rethinking life choices* might be tied to a theme, *emerging self*, that functions as a conceptual bridge between or among codes. In studies using structured interviews, we often find ourselves with pre-existing topics. For example, in a study of indigenous people experiencing climate change in Alaska, we might have anticipated at the outset topics such as *physical health* and *mental health*. These are simply topics based on research questions. They are not themes. To construct a theme, we might review the quotations coded to each code and assess what we perhaps have not noticed in reviewing each code separately. We might discern that across these codes participants address issues of the *self as a marker of climate change*, a thematic bridge that connects the separate notions of physical and mental health.

Braun and Clarke’s thematic analysis method is an iterative process consisting of six steps: (1) becoming familiar with the data, (2) generating codes, (3) generating themes, (4) reviewing themes, (5) defining and naming themes, and (6) locating exemplars. Becoming familiar with data refers to data immersion and iterative cycles of reading, with each cycle generating further insight. Generating codes means coding for as many topics as possible and applying the code to a contextual segment, not just a phrase. Generating themes means sorting the codes into higher-level topics. Researchers might use tables, mind maps, or theme piles to cluster topics into these broader groupings. This phase ends with “candidate themes” and subthemes. Reviewing the themes means interrogating the candidate themes by revisiting the data coded to the component codes. We may determine that the data do not sufficiently support the theme or that there is too much variation across text segments to justify the theme. This may mean renaming the theme or making it a sub-theme of a broader construct. The next phase entails refining the names of themes and ensuring that they occupy the same semantic plane, i.e., that they are conceptually parallel. If the language of most of the themes is broad and abstract (e.g., collectivity and the communal self) but other ideas are more surface-level (e.g., keeping busy, reading a book, playing a game), this may require creating a higher-level construct to elevate the superficial topics to more abstract ones (e.g., suppression and distraction) (see Goodman, 2004). Producing the report means telling the complex story of the themes, first describing the meaning within each theme, with illustrative examples, and then perhaps looking across themes to discern connective takeaways or meta-themes.

Braun and Clarke (2006) state that a theme captures a prominent aspect of the data in a patterned way, “regardless of whether that theme captures the majority experience” (Scharp and Sanders, 2019, p. 1). Though identifying a pattern might entail noticing frequency, it is primarily about meaning making, not underscoring quantity. There is no “hard-and-fast answer to the question of what proportion of your data set needs to display evidence of the theme for it be considered a theme” (Braun and Clarke, 2006, p. 10). In other words, the identified themes address the research question, even if not every participant addresses the theme per se.

In a study of men managing body image and appearance, researchers identified four themes: *men value practicality*, *men should not care how they look*, *clothes are used to conceal or reveal*, and *clothes are used to fit a cultural ideal* (Frith and Gleeson, 2004). Each of these themes addresses the study’s overarching question—how men use clothing. Each theme tells a story based on these abstract concepts. The theme *men value practicality* underscores how men valued the functional nature of clothes, what is “necessary for daily living” (p. 43). Each theme is presented with quotations that add texture to the concept and provide evidence for how the researcher conceptually elevated numerous textual fragments, identified a crystalized pattern or distinguishable shape across different textual accounts. In this way, themes use the idiographic to construct the nomothetic. In some cases, researchers can use the participants’ own language to name the theme, as was the case in a study on whether patients tell their physicians that they are depressed, where themes included “My doctor just picked it up” and “They just check out your heart and things” (Wittink et al., 2006).

Qualitative research approaches

The next section of the chapter presents five established qualitative research approaches: case studies, ethnographies, grounded theories, narrative analyses, and phenomenologies.

Case studies

As others have noted, defining a “case study” is a “definitional morass” given that it can be considered a form of data collection, an approach to analysis, or a type of reporting or write-up, or all these (Gerring, 2007, p. 17; Savin-Baden and Howell Major, 2013). As an approach to qualitative research, a case is intended to have the following properties. First, it is bounded by time and place, such as the months following the rollout of a vaccine in a particular rural county, and has a “real-life,” naturalistic context. However, in the age of virtual spaces and online communities, the notion of “boundedness”—and culture itself—has become increasingly problematic given that individuals can participate in different cultures with complex boundaries simultaneously (Bartlett and Vavrus, 2017). Second, a case study employs methodological triangulation, the use of multiple data collection methods—interviews, focus groups, documents, observations, visual data, and online resources—to contribute to interpretive precision or a comprehensive understanding of an event, episode, organization, or individual. Third, a case has an identifiable context, whose boundaries with the case itself are sometimes difficult to discern, such as a school and the district in which it resides (Stake, 1995, 2006; Yin, 2018).

Case study analysis occurs at the level of a particular semantic plane, or level of abstraction. Analysis can focus on description, such as an account of school bullying at a particular high school, or move into more abstract conceptual territory, such as analyzing identity formation of the bully and victim. The level of abstraction depends on the research question, our intended audience, and whether our aim is rich description—the tangible *who*, *what*, *where*, and *when* of analysis—or also theory building—the *how* and *why* of conceptualizing.

A more explicitly comparative approach would be used in a multi- or comparative case study. Case comparisons can be homologous or heterologous (Bartlett and Vavrus, 2017) where homologous comparisons employ entities having a similar position or structure (such as two colleges with a large number of first-generation students) and heterologous comparisons assess entities that are categorically different or high-contrast (such as a retail store and a clinic) but are studied in order to understand a more abstract phenomenon, such as organizational death. In analysis, researchers would compare data and codes across cases (sites, episodes, or individuals) to investigate similarities and differences and provide evidence for building a logic model or other type of conceptual model, such as a process model of organizational death in a study of dying organizations (Sutton, 1987).

Analyzing a case study requires us to keep track of the complexity of the different units within our data collection, the case itself, and its context. The unit of data collection is often different from the unit or units of analysis (Yin, 2018). We might interview individuals or gather website mission statements to understand an organization, the ultimate unit of analysis. That is, our analysis must always remain attentive to the case itself—drawing conclusions at the case level—and avoid getting lost in the minutia of the units of data collection. Coding for the emotions of individuals in the above example would be of use only if it helps us understand the environment of the organization. Coding for components of participant life histories would be necessary only if the participants themselves were the cases, rather than the units of data collection. However, a particular kind of case study, the embedded case study, would allow us to study smaller units within the larger case, such as classrooms within a school.

Case studies have been characterized as variance oriented, interpretivist, and process oriented (Bartlett and Vavrus, 2017). Variance-oriented case studies, using a post-positivist framing, are concerned with variables and correlations among them (Maxwell, 2013) whereas interpretivist studies attempt to understand participants’ “sense-making” of events or phenomena. In contrast to these, process-oriented case studies tend to seek explanation based on an “analysis of how some situations and events influence others” (Maxwell, 2013, p. 29).

Researchers have outlined different approaches to analyzing case studies, including using a theoretical proposition, using an exploratory approach, developing a case description, and assessing rival explanations (Yin, 2018). Using a theoretical proposition does not necessarily mean a strict prediction involving a dependent and independent variable. Rather, it points to a kind of hunch that we seek to examine qualitatively with multiple data types. Analytic practices in this situation would necessitate linking data to proposition(s) through various strategies, including presenting a descriptive account of a site’s atmospherics or conditions (Yin, 2018). In a practice called pattern matching, we take an identifiable pattern from our descriptive account and compare it to an anticipated or predicted one. Another option, explanation building, involves making an initial theoretical statement, comparing initial findings with the original proposition, revising the original proposition, and repeating this process until one has settled on a refined proposition that matches the data. Yet another practice, the logic model, fleshes out the complex development of events over a period of time. Analytically, this may mean matching observed events with theoretically predicted ones. Across all these practices, analyzing qualitative case studies incorporates many of the strategies and practices employed in generic qualitative research—coding, memo writing, and diagrams.

Case study analysis makes use of methodological triangulation which entails comparing at least two different methods, such as interviews and observations, to assess whether researcher discoveries and participant points of view evident in one methodological practice also surface in the other, for example, whether there are conceptual echoes between interviews and naturalistic encounters (Yin, 2018) (For a discussion of other types of triangulation—data triangulation, investigator triangulation, theoretical triangulation, environmental triangulation—see Denzin and Lincoln, 1998). Triangulating methods allows us to assess convergence, complementarity, or divergence of these different data types, illustrating how evidence across methods supports a claim or complicates it, perhaps further dimensionalizing a topic (Farquhar et al., 2020). Convergence and complementarity strengthen the findings and precision of a case study and address the limitations of relying only on one type of (perhaps myopic) data. Equally valuable, divergence might point to how participants claim a type of behavior or belief that the researcher sees differently through a different method, such as in the context of a real-time observational setting. Though triangulation often aligns with a post-positivist lens,

with appeals to validity and reliability, it can be adopted in a more interpretivist approach, and treated as a kaleidoscope (Flick, 2018), enabling researchers to take on different interpretations of their study at different levels of abstraction (Farquhar et al., 2020).

Memo writing is a tool to systematically compare data types within a case study as well as findings across cases in a multi-case study. Researchers might also use a matrix with different data types on one axis and topics on another axis to further illustrate how a topic (or theme) shows up similarly or differently across these data types (e.g., Rafaeli, 1989).

Ethnographies

As others have noted, many approaches to ethnography emerged in the twentieth century, from researchers studying the internal logics of a holistic culture (Agar, 1980; Malinowski, 1922/1966) to attempts to analyze more interconnected “cultural scenes” (Spradley and McCurdy, 1972). Similarly, anthropologists moved from studying people “outside” their own culture (Park, 1925/1967) to looking at settings within their own culture, such as researchers in the US studying inner city Philadelphia (Anderson, 1999). Contemporary ethnography, especially in recent decades, also introduced efforts to incorporate one’s critical reflexivity into the analytic journey, inquiring how one’s positionality activates a particular ethnographic lens in both participant and non-participant observation and how it contributes to framing the final ethnography.

In entering the field—a school, a hospital, a refugee site—ethnographers encounter multiple ongoing stories, rather than a single cultural account, and concern themselves with verbal exchanges of various types: phatic communion, ordinary conversation, skilled conversation, personal narratives, and dialog (Goodall, 2000). Phatic communion refers to politeness rituals; ordinary conversation to discussion, gossip, or information exchange; skilled conversation to debate, negotiation, or interviews; personal narratives to individual or mutual self-disclosure; and dialog to “spontaneous mutuality” (pp. 103–104).

Ethnographic interviews, as a form of skilled conversation, take place after a researcher has been in a field long enough to be able to ask relevant questions. In analyzing these collected verbal exchanges, the researcher considers the temporal, spatial, and embodied nature of the encounter—body language, vocal inflections, and setting atmospherics. As such, a verbal exchange can be considered as much of an “event” as a cultural practice in the community, blurring the distinction between participant-observation and interview.

Ethnographic efforts function along a spectrum from *emic* (folk concepts) to *etic* (concepts of the ethnographer)—guided by theories of culture and shared meaning—but it is the inductive thrust, the surfacing folk concepts, that leads to the most unexpected findings. Field notes, memos regarding one’s impressions in the cultural spaces, “combine a high level of careful empirical detail with personal asides and impressions” (Mills and Morton, 2013, p. 83). As such, they are a cumulative space inviting the unforeseen to take shape. To refine analysis, ethnographic memos can be organized into types: observational, methodological, theoretical, emotional, and environmental (Gobo and Molle, 2017). In contrast, coding, an optional practice in ethnographic analyses, condenses copious accounts of the cultural group or cultural scenes—observations, interviews, collected artifacts—into meaningful topics. Codes used in ethnographic analyses might include *beliefs* and *values* as well as other established codes such as *routines* (also called “everyday practices”), *rituals*, *rules*, *roles*, *relationships* (Saldaña and Omasta, 2018) as well as *rich points* (speech acts that contain cultural knowledge), *turning points*, *habits of speech*, *myths*, and *actual practices* (or organizational realities) (Goodall, 2000, p. 113). Coding, and analysis itself, is iterative, with initial coding casting a wide net around data, generating many topics—both deductive and inductive—and subsequent analysis engaging more targeted coding. The researcher uses growing knowledge to better assess documented encounters in the field and identify patterns across data, such as power in particular cultural spaces (deCerteau, 1996). Memos and codes together offer two forms of “coherence”: contiguity and similarity (see Maxwell, 2012). Memos can be used to examine cultural spaces as contiguous wholes while coding can be used to identify components of culture (e.g., beliefs) and to assess similarity and dissimilarity within and across them.

Though an ethnography is not replicable in the traditional sense because it would be impossible for another researcher to have the same encounters with the same people in the field and generate the same data, data analysis can attempt to address replicability by developing a codebook. A codebook is a set of identified topics with operationalized definitions. Differentiating between similar codes, such as *sharing information* versus *knowledge building*, can create deeper insights into what shared meanings inhabit the community or group under inquiry. This does not mean that values per se are shared but that the culture as a whole activates a range of values of which others are aware, such as a country with polarized political views. An ethnography might go beyond the data at hand and draw connections between the study’s emerging findings and link them to existing theories on social structures, processes, and outcomes. Furthermore, ethnography is corroborative, relying on more than one data collection method (Wolcott, 2010) (See also discussion of triangulation in **Case studies** section of this chapter.)

Some researchers (St. Pierre and Jackson, 2014) advocate a “post-coding” approach to avoid overly fragmenting data into segments at the expense of a more cohesive understanding. Rather than coding, post-coding practices might include “focusing on occasions and instances” that provide more holistic meaning and writing about those instances as part of rich description (Harrison, 2018, p. 79).

As a final product, an ethnography is an overarching representation of a cultural space (or connected spaces) based on cumulative verbal exchanges, artifacts, and observations. The findings are typically shared in a narrative report that walks the reader through primary themes and illustrative accounts of various interconnected episodes, such as sense-making episodes, risk-taking episodes, face-saving episodes, and crises (Goodall, 2000, p 18; Van Maanen, 1988). In an ethnography of inner-city Philadelphia, anthropologist Elijah Anderson identified constructs, or themes, such as *campaigning for respect*, the *social shuffle*, *self-image based on*

"juice," and the *staging area*. These constructs are an example of applying "inference to a static cultural scene" (Goodall, 2000, p. 94). Agar refers to inferences as the "glue of coherence," what link "different pieces of knowledge and connect knowledge with the world" (Agar, 1980, p. 32). In other words, the evocative language of Anderson's themes provides an interpretive epistemological frame, combining theoretical exploration with evocative description. His ethnography not only identifies abstractions, it also walks the reader through textured accounts of particular youth, such as Tyree's story, which is based on an extended ethnographic interview. Tyree's story is "dramatized in places to represent vividly the intricacies of the code of the street," the unwritten rules of inner-city life, and to provide evidence for the constructed themes (Anderson, 1999, p. 80). Anderson's textured writing bring to mind Haraway's advice that the "only way to find a larger vision is to be somewhere in particular" (1988, p. 590). Synthesizing and reconciling the particular (and its many contradictions) with the holistic is a common objective of ethnographic writing. Visualization techniques for reporting findings include time-ordered displays (understanding causes and contexts of local causality), role ordered displays (showing who does what when), conceptually ordered displays, and agent-based modeling (Gobo and Molle, 2017; Ladner, 2014).

Grounded theories

Grounded theory, developed by sociologists Bernard Glaser and Anselm Strauss (1967), introduced an innovative approach to social and behavioral research that underscored an inductive entry point into initial data engagement, followed by a strategic shift to deduction and more targeted data collection. The ultimate goal of this approach was to theorize based on data—to answer largely "why" questions regarding actions, reactions, and interactions—to attempt to explain what activates, sustains, or destabilizes a complex process. Early grounded theory is sometimes called "objectivist" because it suggested an identifiable, objective theory "out there" in the world. Since then, other forms of grounded theory have been developed, including Straussian grounded theory, which focused on established constructs related to process, including contexts, conditions, antecedents, promoters, actions, and consequences (Corbin and Strauss, 2015; Strauss and Corbin, 2008). Another genre, constructivist grounded theory, developed by sociologist Kathy Charmaz, acknowledged the researcher's role in co-creating data and knowledge production. In contrast to researchers of formal grounded theory, advocates of constructivist grounded theory recognize "multiple realities" and see knowledge as situated within a particular setting or situation in an "ever-changing world" (Charmaz, 2014, p. 132).

Though grounded theory is inductive, researchers nonetheless begin with what have been called "sensitizing concepts," topics based on a discipline or literature review (Charmaz, 2014, p. 30), rather than an "empty head" (Dey, 1999, p. 251). However, these concepts do not direct our inquiry. We are simply aware of them as we begin our intimate reading of data and let the data direct our initial code construction. This phase, called "open coding," allows us to generate numerous ideas, capturing structures and processes as well as creating *in vivo* codes, topics named based on participants' distinctive language. Open coding then moves to focused coding, whereby researchers concentrate on those open codes with the most "analytical reach" (Charmaz, 2014). In interrogating both open codes and focused codes, grounded theorists move to higher levels of abstraction—developing categories—to theorize the data and address variation—how participants might engage a process, such as recovering from a house fire, differently based on shifting contexts and timespans (Charmaz, 2002; Stern and Kerry, 2009). This process might involve returning to the field to collect additional data concentrating on an emerging concept, a process called "theoretical sampling" (Charmaz, 2014; Glaser and Strauss, 1967; Morse, 2007).

Throughout the phases of coding, researchers review quotations coded to the same code or category, a practice called "constant comparison," which, as Glaser and Strauss (1967) note, "very soon starts to generate theoretical properties of the category" (p. 106). This not only allows for theoretical refinement but also encourages researchers to stay close to the data, not to overinterpret based on an underdeveloped understanding of a code. As a mode of rigor, constant comparison engenders a higher level of abstraction (Charmaz, 2014) and can be used in generic qualitative approaches as well. It is a means of precision and a way to avoid drift—losing one's operational sense of a code over time because one has lost track of how it has been applied.

Because grounded theorists are interested in *making sense* of a process—understanding the conditional or evolving contexts in which the process occurs or is transformed—their objectives go beyond practical description to instead grapple with social structures, how processes and individuals are situated, and how processes function in motion. Researchers do not simply move forward into abstract territory; they also go backward into the data itself. This is a shift from induction to deduction as researchers "test" the focused codes on more and more data. That is, the data, including data in the ongoing data collection, become territory that researchers examine with burgeoning hunches. Researchers view the emerging categories provisionally and seek evidence grounded in the data to support, refine, or retire the abstraction. They also seek negative instances and incorporate these occurrences into more overarching constructs. This conceptual elaboration increases the theory's credibility and reach. Researchers might also make use of diagrams throughout analysis to develop conceptual clusters and relationships among codes as they emerge (Keane, 2022; Soulliere et al., 2001).

In some forms of grounded theory, determining a central category or "core concept" is common (Strauss and Corbin, 2008). This summons researchers to conceptualize what they have been hearing across participants and gradually discerning across codes and memos and through constant comparison. As Charmaz (2014) says, a central category is one that "made explicit what I had sensed and understood but had not conceptualized" (p. 146) (Corbin and Strauss, 2015). It takes the foreground as the other categories become supporting entities in the background. In modified versions of grounded theory, there are several primary categories but not necessarily a central one.

Grounded theorists conclude their efforts when additional data confirm the properties of the categories; additional data do not develop the categories (Dey, 2007). This theoretical saturation signals a kind of closure, though the theory will develop as others examine it perhaps using other methods, such as surveys, scales, or other qualitative methods.

In reporting the results of a grounded theory, researchers create products that condense their identified or constructed categories, including perhaps conditional matrices and diagrams that map categories and dimensions (Corbin and Strauss, 2015; Kennedy-Lewis, 2014). A conditional matrix shows the variance of a category on each axis. For example, a matrix addressing survivors of hurricanes might show *perceived luck* on one axis—from high to low—and *trying to live normally* on the other—again from high to low. *Perceived luck* refers to the extent to which survivors claim to be lucky regarding their survivor status while *trying to live normally* captures the degree to which survivors attempt some semblance of a daily routine. The resulting matrix and discussion would show *how* and *why* participants fall in one of the four quadrants; it is one possible product of a study theorizing the process of surviving a hurricane and the variation in the survivors' experiences, but many other kinds of diagrams explicating theory are possible.

Narrative analyses

In narrative analysis, researchers move away from analyzing situations, individuals, and events per se to instead studying the constructed stories—the narrative accounts—of these entities. By becoming a textual event, a story is “detached from the moment it occurred and has assumed consequences of its own” (Moen, 2006; Ricoeur, 1981). The roots of narrative analysis are extensive and have led to numerous lenses for analyzing social encounters as revealed through textual data (see Bertaux, 1981; Clandinin, 2013; Kim, 2016; Polkinghorne, 1988; Riessman, 1993). In this long-established tradition, researchers collect storied data from participants—episodes that individuals present in terms of chronology and plot—in order to construct a meta-story, a higher-level account that incorporates patterns across stories (e.g., see Sarasa, 2015). In seeing data as entry points into storied accounts, researchers depart from more categorical ways of thinking about data and data collection (such as open-ended surveys). However, even in highly structured interview data, which often suppress participant stories, researchers might nonetheless analyze the data with storytelling in mind. Stories provide episodic knowledge—they reveal what participants know without our asking them what they know—and typically take longer to tell than simply sharing an opinion or attitude in more “efficient” forms of data collection, such as open-ended survey responses.

Approaches to analyzing narrative data are varied and have different foci. Analysis might focus on content (what is told), structure (how a story is constructed), or on the narrative's performative aspect (who is the intended audience) (Riessman, 2007). Engaging with narrative data may involve coding its components, such as *story type*, *form*, *genre*, *tone*, and *purpose*. More refined coding structures, such as those outlined by Labov (1972), include: *abstract*, *orientation*, *complicating action*, *evaluation*, *resolution*, and *coda*. *Abstract* encapsulates the reason the story is being told, *orientation* provides details of time and setting, *complicating action* indicates an event that changed the course of action, *evaluation* refers to the narrator's attitude about the event, *resolution* or *result* is the final outcome, and *coda* brings the audience back to the present time. Saldaña (2021) outlines additional analytic practices, including dramaturgical coding, motif coding, and metaphor coding. In dramaturgical analysis, we view life as performance and individuals as characters acting out a plot with an identifiable beginning, middle, and end. Attendant codes include *objectives*, *conflicts*, *tactics*, *attitudes*, *emotions*, and *subtexts* (see also Bogdan and Biklen, 2007). Another especially elaborate option is Thompson's Motif Index. A motif refers to particular details within a tale and may refer to a type of character, action, setting, or object (Thompson, 1932/2022). These include mythological motifs, such as quest motifs, and might be used to assess how certain present-day accounts are congruent with classic literary patterns, providing further insight into how individuals naturally draw from the well of storytelling devices to make claims and describe barriers to their fulfillment.

Despite these established coding systems, Clandinin and Connelly (2000) indicate that their approach is to “find a form to represent... storied lives in storied ways, not to represent stories lives as exemplars of formal categories” (p. 141). Hence, researchers might need to discern in the data those elements that may not align with a previously established code structure. One might also argue that social media is changing how human beings tell stories and these fragmented forms of storytelling—tweets, blogs, and Facebook posts—may require a special form of coding and attention to subtext.

Narrative as chronology, a textual account imbued with plot, invites us to consider how inciting events or a character's actions lead to subsequent events, suggesting a causal link under particular circumstances (Elliott, 2005; Polkinghorne, 1995). Analysis might involve developing a timeline, or an annal (Clandinin, 2013), a logical sequence underscoring the pivotal moments, twists-and-turns, and consequences of the events. After developing a narrative account of each participant, the second level of analysis would involve the “resonant threads or patterns” discernible across transcripts (Clandinin, 2013, p. 132). In one example, “narratives were temporally sequenced, telling of a journey from place to place through time, with key moments in the plot common across the stories” (Goodman, 2004, p. 6). Developing this meta-story involves identifying themes, or resonant threads, that tie together all stories. This re-storying of the stories could also use “cohering metaphors,” such as “rising from the ashes,” or other techniques to identify and name meaningful reverberations across accounts (Ladner, 2014).

Narrative analysis strives to find a meeting ground between the nomothetic and the idiographic. That is, in re-storying, narrative researchers look for broader themes that apply to participants across the data in addition to presenting evocative examples from distinctive personal experience. “In these individual stories, the unique way each participant interpreted his experiences came into view” (Goodman, 2004, p. 6). Quotations from individuals can foreground the unique encounters and language of individuals while the re-storying elevates the individual voices to narrative themes (e.g., Poveda et al., 2004). In Ahlsen et al.'s 2014 article on

men's and women's stories of chronic muscle pain, the researchers focus on a narrative account from one man and one woman, then demonstrate how each of these illustrate the gendered difference of chronic pain evident in the rest of the participants' stories, how women's stories "displayed selves that were actively trying to transcend their former identities and life conditions" while men's stories "tended to display selves that were actively working to find a solution to the problem within the context of medicine" (p. 6). Researchers might also use diagrams to illustrate individual chronologies and a composite diagram to illustrate a common trajectory and perhaps identifiable variations. See process mapping in [Miles et al. \(2020\)](#) and mapping individual narrative plots using space, time, mind in [Ryan \(2007\)](#).

Phenomenologies

Phenomenology is a philosophy, a perspective, and a qualitative research tradition ([Farrell, 2020](#)). As a research tradition, it is aimed at "opening up" our understanding of complex experiential accounts, moving beyond a simple description of participants' opinions, attitudes, and feelings "after the fact." A phenomenological approach is instead aimed at the "living now" ([Van Manen, 2006](#)), at how the "thing-in-itself-as-it-shows-itself in consciousness" (p. 63). In looking "through" what we normally look "at" ([Vagle, 2018](#)), researchers engaged in phenomenology attempt to see through assumptions that have shaped our understanding of the world ([Van Manen, 2006](#)). Phenomenology is engaged in pre-reflective experience, in how we live through encounters *in the moment* such as attempting to speak a new world language or how to program in a technical, computer language. Hence, phenomenological interviewing attempts to invoke the "living moment of immediate experience" ([Van Manen, 2006](#), p. 59)—something that highly structured interviews are not designed to do—rather than post-reflective theorizing, conceptualizing, and polemics. Phenomenology is guided by the concrete, direct contact with the world, rather than an objectification of it and is focused on the phenomenon more than on the psychological self of the individual. Various genres of phenomenology have been developed, including transcendental phenomenology ([Husserl, 1970](#)), personalistic phenomenology ([Scheler, 1970](#)), and ontological phenomenology ([Heidegger, 1962](#)).

Even though experiential accounts of a lived experience are not identical with the "living now" itself, we use open-ended interview data as an entry point into the experience and as content that we can use for analytic reflection. These accounts can come in the form of phenomenological interviews—conversations designed to invite participants to walk us through an experience—or in written accounts provided by participants. In either case, we are interested in the experience from the "inside," how individuals inhabited space, how things sounded, what stood out as vivid in the moment.

In analysis, researchers take on both description and interpretation, uncovering evocative moment-by-moment experience. However, creating standard procedures for phenomenological analysis is antithetical to the approach given by phenomenology. Each study has its own approaches to uncovering the phenomenon, to making its "essence" apparent. Nonetheless, this chapter will attempt to provide guidance on how a researcher might proceed to describe and interpret a phenomenon. The analytic labor of phenomenology involves reducing the experiences of the phenomenon to its identifiable structures across individuals. [Van Manen \(2006\)](#) offers different possibilities of reductive reflection: thematic reflection, linguistic reflection, etymological reflection, conceptual reflection, exegetical reflection, and hermeneutic interview reflection (p. 312). This list gives us options in our attempts to condense textual accounts into meaningful parallels across participants, opening up the phenomenon thematically and linguistically.

Rather than coding, developing taxonomies, or assessing the frequencies of topics, phenomenologists might instead first mark transcripts to identify "meaning units." These are evocative paragraphs that bring us into the living now. We might assign titles to these units to not only help organize them but to begin the process of condensing the data to its essential meanings. The title might be part of the participant's own language as a way of elevating particular evocative language. Next, a researcher might write a reflective memo on the meaning unit capturing the implications of the paragraph, then title the memo. [Van Manen \(2006\)](#) outlines an intermediate step whereby the original paragraph is turned into an "anecdote," (p. 29) with much of the same language as the original but with unnecessary detail removed. The anecdote is intended to focus on the details of the phenomenon. A reflective memo could then be written based on the anecdote, with an eye to reducing the datum to its phenomenological essential meanings. If writing this memo proves challenging, the researcher might, as Van Manen suggests, write a reflective sentence of each sentence of the original paragraph or anecdote to identify moment-by-moment significance. This invites the researcher to slow down and think more intentionally about the experience as it is unfolding. As we move through data and write more memos, we might also notice how participants engage time, physical settings, and other elemental structures of the phenomenon. More specifically, we might assess meaning at the level of the transcript, paragraph, or sentence, writing memos to keep track of our reductive reflection.

The product of a phenomenology is not theory but highly relevant description. Phenomenologists gather together perceptions and sensitivities across participants' open-ended interviews and synthesize these data into a structural description of the phenomenon. This description is less idiographic than it is summative of the common structures that hold together the phenomenon as a distinctive unfolding of moments. Hence, we might outline a phenomenological structure, organized by time or other common features. For example, a phenomenology of living through a hurricane might locate common moments, embedded in time, such as incremental awareness of danger and survivors' attempts to validate their fears by communicating with a neighbor or stranger (For other examples, see [Callister and Cox, 2006](#); [Eddles-Hirsch, 2015](#); [Mihás, 2019](#)). A product of a phenomenology might also include central features—a list of statements about the phenomenon that allows us inside of it

(Wertz, 2011). Some researchers might even use found poems or other artistic forms to capture the living now of the phenomenon as it is revealed across data.

Conclusion

Deciding on a qualitative research tradition and analytic approach depends on the research questions and the intended scope and analytical depth of the inquiry as well as on the receiving audience for the research. Research traditions can also be blended in innovative ways that fuse two or more approaches, such as using narrative inquiry to build a grounded theory (see Williams and Keady, 2012). Claiming a particular research tradition should come from attention to one's ontological and epistemological assumptions—the amniotic fluid of the inquiry—as well as from the research question itself. Ontological and epistemological considerations point to what will be considered “evidence” for a given study and whether textual data represents reality or generates its own narrative reality.

If the researcher is viewed as a reliable agent of logic (Vagle, 2021) who, with sufficient evidence, can discern an event or situation, then collecting qualitative data can sufficiently represent the reality they seek to uncover. But if one sees reality as a negotiated space co-constructed continuously, then this perspective alters one's stance in relation to the generated data and findings. This is why constructivist grounded theorists make no claims to stand outside the theory; they are aware that the interviews (or other data forms) are co-constructions, not a precise mirror of an objective reality. Narrative researchers, too, are aware that interviewees are telling a story *to the interviewer* in a manner than may differ from how they perform the story to others. In phenomenology, epistemological concerns also lead researchers to bracket their own experiences of the phenomenon and to un-learn what they thought they knew (Vagle, 2021). Epistemological paradigms also determine, in part, the language of the analysis—a constructivist researcher might talk about “constructing” themes whereas a pragmatic researcher might discuss “identifying” them. More importantly, knowledge might be discerned as derived from direct observation (discovered in a single reality “out there”), co-constructed with participants, or derived from a deep analytic dive into the intentionality of subject-object. Hence, one's reporting of what one knows, has constructed, or has found will be shaped by one's epistemological positioning. Researchers should consider these assumptions when embarking on analysis to not only understand how to share findings but to communicate what constitute and what problematize them.

What is qualitative content analysis?

The chapter gives an overview on theoretical background and specific techniques of qualitative content analysis. Its role in qualitative research is described, central elements of definition introduced, and basic characteristics discussed. The importance for educational research is outlined, and the historical and methodological background described. We present two basic procedures, inductive category formation and deductive category assignment, by step models and by an example from educational research. Differences to other approaches to qualitative content analysis are worked out. An open access software program especially for our techniques of qualitative content analysis is presented.

First, I want to give a definition and characterization of the approach. Qualitative content analysis (cf. Mayring, 2015b, 2020, 2021; Kuckartz, 2014) is a methodological approach to text analysis mainly in social sciences, which can be used in empirical research projects working with textual material like interview or group discussion transcripts, open observational protocols (field notes) or document analyses (files or webpages for example). In a systematic bibliometric analysis of the literature and research databases FORIS, SOLIS, Sociofile, Psynindex and MLA, Titscher et al. (2000) found open content analysis as the most frequent text analytical procedure with 39% from 1621 citations. Qualitative content analysis was followed by conversation analysis (21%), standardized content analysis (19%), grounded theory (12%), objective hermeneutics (5%), and ethnography (2%). Carrera-Fernandez et al. (2014) found that particularly in psychology (based on the Web of Science database) the qualitative content analysis was by far the first choice of analysis procedure, followed by grounded theory, discourse analysis and action research in their qualitative orientated journal article analysis.

What are the central characteristics of qualitative content analysis? I want to outline four points:

- The qualitative content analysis approach (the same in quantitative content analysis) is *category-based*, that is its distinguishing feature. Categories refer to aspects within the text, which put the meaning of those aspects in a short textual form. Text analysis is, therefore, restricted to the category system. Text contents that are not addressed by the categories or holistic impressions are not considered or would have to be addressed with a further content analytical conduct or other text analysis methods. In so far it is a selective procedure in contrast to a holistic text understanding.
- The qualitative content analysis procedure is *research question oriented*. Text analytical questions (possibly several) are derived from the main aims of the research project. These questions should be answered at the end of the analysis. This clearly distinguishes the qualitative content analysis from other more open, explorative approaches such as grounded theory.
- Qualitative content analysis is characterized by strict *rule orientation and systematic ongoing*. Process models enable the procedure to be described step-by-step, and this has proven itself in previous research processes. The specific rules for each technique are reviewed in a pilot study and should not be changed after that.
- Qualitative content analysis is an approach of *mixed methods*, standing between pure qualitative and pure quantitative ongoing. The first step to assign categories to text passages or to develop categories from text passages is a qualitative-interpretive operation, the comparing, accumulating text passages with similar categories, analyzing frequencies of categories means a quantitative ongoing (the second quantitative step is not obligatory in qualitative content analysis, but mostly obvious).
- A central quality criterium for qualitative content analysis consists in high *coder agreements*, which means that several procedures of categorization of the same material should lead to similar results. Intra-coder agreement, similar to reliability (retest reliability), means that the same content analyst restarts with coding after finishing all material. Inter-coder agreement means passing the material (or at least a selection) to a second person, a measure of objectivity of the analysis. We would not expect an identical result (e.g., in the wordings of inductive categories), but a similar solution.

We can summarize: Qualitative content analysis is a systematic category-based set of techniques for analyzing texts with strict theory-based rules, containing qualitative and quantitative steps of analysis.

The relevance of qualitative content analysis for educational research

Qualitative content analysis can contribute to substantial educational research for several reasons. First, we have to consider that texts represent an important part of empirical material, coming from the data collection process. A pure quantitative research strategy restricts itself to data collection methods like test, measurement, closed questionnaire and closed observation because they produce numerical data which can be analyzed statistically. But educational processes often can only be understood if participants are putting their inner condition, their emotions, cognitions, motivations into speech, communications with the researchers in an open-ended form. And all that leads to texts which must be analyzed.

Texts occur in educational research in different forms:

- Open-ended interviews represent the gold standard in qualitative research. A more or less elaborated interview guide contains the themes or topics, deduced from the research question(s), the interviewer introduces them in his or her own language into the interview and the interviewee can react to them freely and is not reduced to choosing from predefined answers. There are several forms of open-ended interviews, like focused interview or narrative interview. Valuable empirical material in educational research can come from interviewing teachers or parents about their educational aims or letting them report successful or problematic educational situations, it can come from asking students about their learning motivations or emotions at school.
- Group discussions or focus groups bring together several participants and present them a list of discussion topics. A moderator is leading the discussions, trying to foster the participation of all participants and to thematize contradictory statements. Group discussions are very effective in educational evaluation research.
- Open-ended questionnaires give the participants the possibility to reflect their answers unhasty. They are recommended for research questions which afford elaborated appraisals or detailed statements.
- Student learning diaries, instructed by guidelines or in a free form, are a rich source of insight in educational processes.
- Open observational studies or field studies imply a longer participation in an educational field (school, family, community). The researcher records his or her observations in a protocol or in field notes.
- Document analysis works with textual material from files, documentation systems, web pages or other forms of relevant fixed texts which the researcher has found (unobtrusive measurement). In schools exercise books or essays written by pupils can be an example.

In all those cases textual material is generated by data collection (in interview studies usually as transcripts). Qualitative content analysis represents one form of systematic analysis of those empirical materials.

A short history of qualitative content analysis

Systematic techniques of content analysis had been developed in the first half of 20th century in communication science to analyze the huge amounts of textual material coming from modern mass media like newspapers, journals, radio transcripts (Krippendorff, 2019). Therefore they were conceptualized quantitatively: "Content analysis is a research technique for the objective, systematic and quantitative description of the manifest content of communication" (Berelson, 1952, p. 18). Because of the focus on countable aspects of texts the analysis was limited to the manifest content and neglected latent meanings. A series of systematic, rule-guided and intersubjective verifiable procedures were developed (Gerbner et al., 1969):

- Simple frequency analysis defines certain text elements and counts them. Formal elements, headings or topics could be as well in the focus.
- Complex frequency analysis determines variables and defines indicators for them in the text material. Examples are variables like speech disturbance in psychotherapy protocols or ideological style in newspaper commentaries. The indicators are counted and summarized to variable values.
- Contingency analysis is testing for common occurrences of categories within defined text segments (sentence, paragraph, newspaper article). This could be in form of frequent word clouds or complex structures of associations (central term together with positive or negative evaluative terms).

In any case the categories must be defined in advance and the occurrences of categories in the text are registered automatically, usually by computer programs. However, quantitative content analysis leads to several problems, for example:

- Multiplicity of meaning (e.g., "madly" in the colloquial meaning, say, of "very"; or "madly" as pertaining to psychological disturbance)
- The nuances and connotations conferred on terms by the context
- Contextual modification of meaning (for instance in the case of "no anxiety," "little anxiety" and "a lot of anxiety," "anxiety" will be counted once in each case)

- The contextual relationship of the term counted (e.g., with “I am afraid of X” or “X is afraid of me,” “afraid” is counted once in each case)
- The problem of pro-forms (e.g., with “I didn’t notice any of that” the computer does not know what “of that” refers to)
- Dialect expressions (which occur in interview scripts regularly) need a great deal of re-working

Those problems led to the development of procedures of qualitative content analysis. The central idea is to maintain the logic of systematic text analysis, adapted as well for large text corpora, but to define the step of approaching categories to text passages as rule-guided interpretive procedure.

Methodological backgrounds

The content-analytical rules for the individual techniques are not arbitrary but have a solid theoretical foundation in the processes of everyday text analysis. In particular, regarding how these processes have been examined in cognitive psychology and psycholinguistics. For summary and inductive category formation, these are reductive operators (omission, generalization, construction, integration, selection, and bundling; Mandl, 1981), on which the gradual reduction of text segments is based. For explications, it is rather context theories from linguistics, whereas for deductive category applications, reference is made to the categorization theories from general psychology and language development research (Mayring, 2022). The result of this was that the exact wording for a human-readable general category requires an explicit definition (definition theory), a cognitive anchoring in typical examples for the category (prototype theory), and rules to demarcate the categories from one another (decision bound theory, Murphy, 2002). These coding guidelines are the basis for the three-part coding—definitions, anchor examples, and coding rules—applied in the procedure that I recommended. Thus, when trying to determine content-analytic rules, I try to use strategies that draw on the everyday handling of texts, a method that is common in qualitative research, for example, when linguistic approaches to storytelling in everyday life are employed in the rules for narrative interviews.

Basic techniques

The techniques of qualitative content analysis which we present here had been developed in 1980 (cf. Mayring, 2000, 2022) and refined since then into three groups of procedures:

Reducing procedures: The object of the analysis is to reduce the material such that the essential contents remain, in order to create through abstraction a comprehensive overview of the base material which is nevertheless still an image of it.

Explicating procedures: The object of the analysis is to provide additional material on individual doubtful text components (terms, sentences, ...) with a view to increasing understanding, explaining, interpreting the specific passage of text.

Structuring procedures: The object of the analysis is to filter out particular aspects of the material, to give a cross-section through the material according to pre-determined ordering criteria, or to assess the material according to certain criteria. In those procedures the categories are formulated in advance in the sense of a deductive category assignment.

These basic forms, however, must be further differentiated before an exact description of procedures is possible. In addition to the usual summaries, the same ongoing process is useful for inductive category formation; a criterion for the categories is defined and aspects of this criterion are stepwise gathered in the material. Forms of explication are possible which use the textual context for the elucidation of a specific text passage (narrow context analysis); however, the most common method of hermeneutical interpretation is to use further material beyond the textual context for explication (broad context analysis). With structuring, too, subgroups must be distinguished. The categories which are brought deductively to the material can consist of a list of aspects (nominal scale). Or the categories form an ordinal scale (e.g., more—less; positive—neutral—negative) and serve as a rating procedure for the text. In addition, some mixed procedures have been described (Mayring, 2021, 2022). One such is that in content structuring or theme analysis the material is deductively ordered to categories and within each category material an inductive process of category formation is performed. Type analysis is a similar procedure where categories in the first step have to meet a typologizing criterion (typical types, extreme types, frequent types, theoretical types). In category refinement a deductive category system is modified and supplemented with new categories in an inductive way. Parallel forms execute several procedures in one passage through the material.

Through this differentiation we arrive at ten distinct forms of analysis (cf. Mayring, 2020, 2021, 2022):

Reductive:

- (1) Summary: The whole text is reduced step by step to its core content.
- (2) Inductive category formation: Categories are formulated from the text, following a selection criterion and an abstraction level.

Explicating:

- (3) Narrow context analysis: An unclear text passage is explained by systematically collecting related content within the whole text.
- (4) Broad context analysis: An unclear text passage is explained by systematically collecting related content within the text and from additional material.

Structuring/Deductive:

- (5) Nominal categories: Predefined categories from an unordered list are assigned to the text.
- (6) Ordinal categories: Predefined categories from an ordinaly ordered list are assigned to the text.

Mixed:

- (7) Content structuring: Central themes are extracted from the text, and the referring text passages are summarized.
- (8) Type analysis: Typical aspects of the text are extracted, and the referring text passages are summarized.
- (9) Category refinement: A deductive category assignment is extended by adding new categories.
- (10) Parallel forms: Several inductive or deductive techniques are applied simultaneously to the text.

These procedures have been described extensively elsewhere (Mayring, 2021, 2022). We now demonstrate two central techniques of Qualitative Content Analysis: inductive category formation and deductive category assignment (structuring).

Inductive category formation

On the basis of summarizing qualitative content analysis, a technique for inductive category formation can be developed. We have underlined that category definition is a central step in content analysis. There are two possible procedures: deductive category definition tries to develop categories out of theoretical considerations, with theories or theoretical concepts used in a process of operationalization in direction of the material; inductive category formation develops categories directly out of the material. For qualitative content analysis the second is very fruitful. The ongoing inductive process has great importance within qualitative research. It aims at a true description without bias due to the preconceptions of the researcher, an understanding of the material in terms of the material. Inductive category formation is a central process within the approach of Grounded Theory (Strauss, 1987; Strauss and Corbin, 1990), which they call “open coding.” They developed many rules of thumb for open coding, and they recommended a systematic, line-by-line procedure. For content analysis, nevertheless, inductive category formation has to be more systematic. And it can use the same logic, the same reductive procedures, as in summarizing content analysis. The following process model (Fig. 1) will now be explained.

Fig. 1 Process model of inductive category formation.

Within the logic of content analysis, the level or theme of categories to be developed must be defined previously. There has to be a criterion for the selection process in category formation. This is a deductive element and is established within theoretical considerations about the subject matter and the aims of analysis. The second basic content analytical rule for inductive category formation is the establishment of the abstraction level. This comes from summarizing content analysis which reduces the material from one abstraction level to the next. If this level is not defined the categories remain chaotic, out of order. After those two rules are determined, the material is worked through line by line. The first time that material is found fitting the category definition, a category must be constructed. A term or short sentence which stands as near as possible to the material serves as category label. The next time a passage fitting the category definition is found it has to be checked whether it falls under the previous category, in which case it can be subsumed under this category (a reductive process); if not, a new category has to be formulated.

After working through a good deal of material (c. 10–50%) no new categories are to be found. This is the moment for a revision of the whole category system. It has to be checked whether the logic of categories is clear (e.g., no overlaps) and whether the level of abstraction is adequate to the subject matter and aims of analysis. Perhaps the category definition should be changed. If there are any changes in the category system, of course the complete material has to be worked through once again. After this analysis we have a set of categories to a specific topic, connected with specific passages in the material. The further analysis can go different ways: the whole system of categories can be interpreted in terms of the aims of the analysis and used theories; or the links between categories and passages in the material can be analyzed quantitatively (e.g., we can look at those categories occurring most frequently in the material).

For example, in a study on learning emotions (Glaeser-Zikuda and Mayring, 2003) we analyzed open-ended interviews and daily diaries on concrete learning experiences of 24 students of eighth grade. With inductive category formation we built up categories concerning positive learning experiences. We generalized those categories on a medium level of abstraction. Here are the most frequent categories:

C1: Happy about the interesting learning activities today	(21 occurrences)
C2: Happy to master the subject and having understood everything	(21 occurrences)
C3: Amazing subjects in the lesson (literature, poems)	(16 occurrences)
C4: Enjoyed the positive feedback by the teacher	(14 occurrences)
C5: Nice group work or partner work	(11 occurrences)
C6: Interesting problems (electricity) in the lesson	(3 occurrences)

Those inductive categories give an impression about positive emotions in learning processes. In a second step we found two main categories within this list: positive emotions about the learning processes (C1, C2, C4, C5) and positive emotions about the learning content (C3, C6). We then compared the occurrences of those main categories between the two groups of high and low achievers and found a correlation between positive emotions about learning processes and high classroom achievement. That means that it seems to be more important for good teaching to associate positive emotionality with successful learning processes than with learning content.

Deductive category assignment

This is the content-analytical method which is probably most often used. It has the goal of extracting a certain structure from the material. This structure is brought to bear on the material in the form of a category system. All text components addressed by the categories are then extracted from the material systematically. If one wishes to describe the structuring procedure quite generally, a few points are especially important: the fundamental structuring dimensions must be exactly determined; they must derive from the research question and must be theoretically based; these structuring dimensions can be further subdivided, split up into individual features or values; the dimensions and values are then brought together to form a category system.

The particular categorization of a given material component is something that must be determined precisely. A procedure for this, based on everyday life processes of categorization, has proven useful (cf. Ulich et al., 1985). Within developmental psychology (learning of categories in speech development) and within general psychology (categorization theories, cf. Murphy, 2002) it has been shown that categories are imagined in form of explicit definitions, prototypes and demarcation rules. So, a category can be defined best if all three determining approaches are used:

- **Definition of the categories** It is precisely determined which text components belong in a given category.
- **Anchor samples** Concrete passages belonging in particular categories are cited as typical examples to illustrate the character of those categories.
- **Coding rules** Where there are problems of delineation between categories, rules are formulated for the purpose of unambiguous assignment to a specific category.

Fig. 2 Process model of deductive category application (structuring).

Test extracts are taken from the material to check whether the categories are at all applicable and whether the definitions, anchor samples and coding rules make category assignment possible. This trial run-through, like the main run-through proper, is subdivided into two steps of operation. First of all, the text passages in the material are marked in which the category concerned is addressed. These “points of discovery” can be marked by noting the category number in the margin of the text or through differently colored underlines in the text itself. In the second step the material thus marked is processed in accordance with the structuring intention (see below) and copied out of the text. As a rule, this trial run-through results in a revision and partial reformulation of the category system and its definitions. Now the main material run-through can finally begin, again split up into the two stages of marking the points of discovery and extracting and processing them. This general description of a structuring content analysis can be shown in a procedural model (Fig. 2).

To further explain the procedure for all techniques of Qualitative Content Analysis, rules of interpretation have been formulated. Those step-models and content analytical rules are explained in detail in Mayring (2021, 2022). Here we just demonstrate the idea of rule-orientated text analysis.

In the above-mentioned study on learning emotions (Glaeser-Zikuda and Mayring, 2003), we developed a category system with 3-point ordinal scales (much—some—no) for four central learning emotions: joy, interest, anxiety and boredom. We established a coding guideline containing definitions, anchor examples and coding rules for those 12 categories. Every student was coded one value (much—some—no) for the four emotions. We divided the sample into high and low achievers and compared the emotion results. In the material (interview, learning diary) of high achievers, significantly more joy was coded ($p < 0.05$; Mann-Whitney- $U = 42.00$), more interest ($p < 0.05$, Mann-Whitney- $U = 12.50$), but no significant difference in boredom was found.

Software support

In addition to existing approaches in computer-assisted qualitative analysis software (see e.g., Silver and Lewins, 2014), a purpose-made software was necessary. This was because the separate processing steps involved in qualitative content analysis are difficult to implement in conventional and commercial programs. For example, it is not easy to keep the central content-analytical rules (category definitions, levels of abstraction, coding guidelines) constantly visible alongside the analysis. This only works to a limited extent using the memo function in MAXQDA or ATLAS/ti, and that actually belongs to the grounded

theory methodology. A table notation, central for summary and coding guidelines, can only be achieved partially. For these reasons, we have developed our own software program QCAmapp (Fenzl and Mayring, 2017; Mayring, 2021), which offers the following advantages:

- Free use
- Interactively guiding users through the steps of content analysis
- Templates for the individual techniques such as summary, inductive category development, and deductive category application
- Templates for the individual analysis units that should be defined as well as content analysis rules
- Ongoing maintenance and further development of the program as a web application
- Interactive possibilities for raters, also for intercoder comparisons

The interactive nature of the program ensures that the essential steps of the qualitative content analysis are actually carried out. The program has been used in more than twenty thousand projects since 2013. In future versions, we plan to integrate video analysis into the program.

Different versions of qualitative content analysis

Finally, I want to compare the outlined approach with similar methodological developments (cf. Mayring, 2020). Within media analysis, Altheide (1996) has developed a procedure (“ethnographic content analysis”) working with deductive categories (codes), which were refined in the process of analysis. Then he summarizes the results for each category. This has similarities with our approach but is not so rule oriented as Qualitative Content Analysis. In the USA there exists an approach coming from quantitative content analysis which is called Codebook Analysis (Neuendorf, 2002). It is a deductive category application procedure, which defines all categories in the codebook and gives examples from the text. But this definition is not so systematic as the coding scheme (definitions, anchor examples and coding rules) in our procedure. In some ways similar is Thematic Text Analysis (Stone, 1997), which looks in the text for central themes, using theoretical preconceptions or empirical word frequencies and word contingencies. In both cases Qualitative Content Analysis defines the procedure more precisely. The related concept of Theme Analysis covers more free, phenomenological procedures (Meier et al., 2008). Some similarities can be found between Qualitative Content Analysis and text analysis following Berg (2004). He describes deductive (“analytic”) and inductive (“grounded”) categories which have to be defined explicitly, but it remains unclear how this has to be done.

The conceptual design of the qualitative content analysis by Kuckartz (2014) is an approach, which mixes systematic methods of qualitative content analysis from our conception with broader open interpretive procedures. As a first step, Kuckartz’s method begins with an initial processing of the text, which is hermeneutically interpretive and involves reading the complete text. While doing so, important points for the research question should be marked, yet this remains relatively vague. This should lead to case summaries and memos about the text. Then a profile matrix should be created, consisting of a table that, for example, should contain central topics and selected passages from each interviewee’s transcription. Only then does the analysis begin with basic content analysis methods, again requiring several text processing repetitions. This is only possible with smaller amounts of text and would, according to my calculations, require more than half a year to work on the text alone for an interview study with 30 people. In my opinion, this throws away some of the potentials of content analysis. Besides, the proposal actually represents a mixed form of different text analysis approaches that are not justified, since some steps are very openly interpretative and not very verifiable, and other steps are strictly guided and more verifiable. This could also be a problematic blending of different positions in scientific theory (constructivism with post-positivism). From my point of view, it also poses a contradiction because on the one hand, summaries should be created, which is a rather explorative process, but, on the other hand, a question is set out on which all analyses should be based. Furthermore, it is not clear which role the (very complex) summaries should play. Finally, basic methods of qualitative content analysis are presented that are based on my work, but only represent a selection of the repertoire and does not offer supporting argumentation for this selection. From the techniques I presented, Kuckartz (2014) selected three (content, type building, and scaling structuring, see **Basic techniques** section of this chapter); however, it is not clear why these three were preferred to the other techniques that I developed. Furthermore, when discussing case summaries, he does not refer to the content-analytical procedure described in **What is qualitative content analysis?** section and, for example, in my opinion, fails to take advantage of one of the most important inductive category formation techniques available.

The concept of qualitative content analysis by Schreier (2012) seems similarly problematic and confusing to me. Here the process is described in such a way that a higher-level category system (coding frame) is developed first, the categories are then defined and pilot-tested, and finally applied to the material in a further step. I think this is far too time-consuming in the case of inductive category development. Instead, I suggest both developing the categories and assigning them to the text in a single pass through the material. In the case of Schreier’s description of inductive category development, a detailed coding guide (category definition, anchor examples, and coding rules) is not necessary; I only designed it for deductive category applications. Theory-based definitions for each category are not feasible here since categories for the material are developed ad hoc. Anchoring examples are not necessary because the text passages were developed with the categories. Thus, they are marked already and represent the anchoring example. Only coding rules for setting boundaries were addressed, but that would not have been necessary

either, as these would have to be carried out for each inductive category. Usually, those categories are summarized during the analysis or hierarchically structured (main categories). Schreier then describes four different approaches for the development of inductive categories (data driven): summary, grounded theory coding, subsumption, and contrasting. This also seems somewhat implausible and of only limited use. Summarizing is usually far too complex for inductive category formation since all the material must be considered. I only regard summaries to be useful if the material is very homogeneous and the question is open and descriptive. In contrast, once a category definition and a defined level of abstraction have been established, inductive categorization continuously creates new categories on a previously defined topic. Grounded theory coding follows an open, exploratory, theory-building strategy that should be accompanied by further processes, in particular, case contrasting, theoretical sampling and memo writing. That differs from the content-analytical inductive category formation since a category definition is already specified as a selection criterion, and categories are formulated in the sense of a descriptive design (not exploratory, categories still have to be checked). Subsumption, the third inductive strategy according to Schreier, and does not in my understanding lead to inductive categories at all, but only assigns further text passages to previously developed inductive categories, if so desired, to reach category frequencies.

In comparison with those text analytical approaches, Qualitative Content Analysis seems to be most broad (describing a wide set of different procedures) and most exact (prescribing clear step models and analytical rules). So Steigleder (2008), after a praxis test of Qualitative Content Analysis, concludes that “it has proven its worth in many studies. With its different techniques of analysis and its methodological concept it is excellently adapted to analyze qualitatively collected material” (Steigleder, 2008, p. 197). But it should not be argued that Qualitative Content Analysis is the only legitimate text analysis procedure. It depends on the concrete research question and the quality of the material which procedure should be chosen. If use of the strict category relatedness and rule orientation of Qualitative Content Analysis neglects important deeper aspects of the material (e.g., repressions in the sense of psychoanalysis), then other procedures (e.g., psychoanalytical text interpretation) would be more adequate.

Final remarks

Qualitative Content Analysis enables a systematic analysis of textual material especially important for educational research. Transcripts from open ended data collection methods present insights in inner processes of learning and development.

Especially because of its intermediate position between qualitative and quantitative analysis, qualitative content analysis appears to be an important methodical approach. It represents a mixed methods analysis, combining qualitative steps (assignment of categories to text segments) and quantitative steps (analyzing category frequencies). It provides a series of concrete techniques (summary, inductive category formation, explication, deductive category assignments, mixed techniques) for different research questions approaching texts.

The central element of qualitative content analysis is its rigor, comprehending clear units of analysis, step models of techniques, and final checks for coding agreements. By this systematic, qualitative content analysis can meet scientific quality criteria, representing an alternative to more free and less controlled interpretation in text analysis.

Qualitative data provide important insights into behavioral and perceptual factors often missed in quantitative research. In other words, qualitative data are often referred to as providing the “how”, while other typically quantitative data provide the “what” (Teti et al., 2020; Vindrola-Padros et al., 2020). A lesser discussed phenomenon is how the utility of such qualitative approaches is bound by timely delivery of study findings. Timeliness is a core feature which determines the extent to which research findings can be used to inform decision-making processes and be successfully translated into policy and practice (Grasso, 2003; McNall et al., 2004; McNall and Foster-Fishman, 2007; Vindrola-Padros et al., 2021; Vindrola-Padros, 2021a,b; Vindrola-Padros and Johnson, 2020). In some instances, research topics are particularly time-sensitive and can only be studied through rapidly implemented research (Johnson and Vindrola-Padros, 2017).

Understandably, this is the most common reason for enlisting rapid qualitative research methods, whether this is in the form of a study with a compressed timeframe, or integration of regular feedback loops within a longer-term project—both serve to present findings at strategic timepoints (Vindrola-Padros et al., 2021). Beyond timeliness, rapid qualitative methods can also enable mid-course program corrections, adaptation to changing circumstances due to flexible study designs, and communication with stakeholders (Vindrola-Padros et al., 2021). While time reduction tends to be the most frequently cited reason for the use of rapid techniques, a systematic review found five other reasons for adoption of such methods: to reduce cost, to increase the amount of collected data, to improve efficiency, to improve accuracy, and to obtain closer approximation to the narrated realities of research participants (for example, by analyzing findings directly from audio data to avoid transcription errors) (Vindrola-Padros and Johnson, 2020). Hence, long-term fieldwork might not be required for all research topics or contexts and can even limit the contributions of qualitative methods to inform changes in policy and practice (Beebe, 2014; Pink and Morgan, 2013; Abramowitz et al., 2015; Johnson and Vindrola-Padros, 2017).

Rapid qualitative research is becoming more widely used in contexts such as healthcare and education (Vindrola-Padros et al., 2021). Rapid data collection and analysis approaches are used to capture complexities surrounding service provision, the social and cultural factors shaping service use and delivery, and the nuanced practices of service provision in short time frames, which in turn, can be used to inform and shape implementation and future service design (Vindrola-Padros and Vindrola-Padros, 2018). More specifically, rapid qualitative data can be responsive to: local contexts for drawing on community resilience mechanisms; rumors and associated population-level behaviors; societal tensions which disproportionately affect marginalized populations; and organizational challenges of response efforts, highlighting associated gaps and omissions (Johnson and Vindrola-Padros, 2017).

While rapid qualitative methods can be used in a wide range of settings, topics and populations, there will always be questions and contexts that are not suitable for rapid research approaches (Vindrola-Padros and Johnson, 2020). Furthermore, even in contexts where rapid research may be beneficial there are a series of situations in which rapid qualitative studies should be avoided (Vindrola-Padros, 2021a; Vindrola-Padros and Johnson, 2020), such as: when researchers are being asked to cut corners which may violate the quality or ethical standards of research; when study findings may have (intended or unintended) negative

consequences; when researchers will not be able to access people or spaces required to carry out data collection; when time and resources are too constrained; when there is a lack of existing evidence to help guide the study; when there is a lack of willingness from researchers to engage with new methodologies or techniques; or when researchers lack the experience required to carry out rapid research.

Aims and structure of the chapter

This chapter is designed as an introduction to rapid qualitative research. Having briefly outlined the “when” and “why” of rapid qualitative research, this chapter progresses to defining rapid qualitative research before providing an overview of a wide range of rapid qualitative approaches and their history. The chapter then discusses five key features of rapid qualitative research. The challenges of rapid qualitative research are briefly put forth, while signposting to potential solutions. The chapter concludes with a discussion of the future of rapid qualitative research.

This chapter aims to equip the reader with knowledge on:

1. When and why rapid qualitative research methods are appropriate
2. How to define, or identify, a rapid qualitative approach
3. The various rapid qualitative approaches, their key features and origins
4. The challenges associated with rapid qualitative approaches

Definitions of rapid qualitative research

Rapid qualitative research is an umbrella term, analogous to “long-form qualitative research” which captures many study designs and approaches to collecting and analyzing data within short study timeframes. Common rapid qualitative research approaches include rapid ethnographic assessments (REAs), rapid assessment procedures (RAPs), rapid qualitative inquiry (RQI), rapid ethnographies (including quick, focused, and short-term ethnographies), and rapid evaluations (including rapid feedback evaluation, real-time evaluation, and rapid assessment). Each of these approaches have their own features, yet some authors have attempted to provide an overarching definition for this field.

McNall and Foster-Fishman (2007) reviewed a wide range of “Rapid Evaluation and Appraisal Methods” (REAM) and hypothesized that these shared the following features:

- Are conducted over a short timeframe (weeks or months)
- Often include participants or members from the community in the phases of study design or implementation
- Combine multiple research methods and triangulate data during data analysis
- Collect data and undertake analysis in parallel, using insights gained from analysis to iteratively shape the data collection process.

Beebe’s definition included some of the features outlined by McNall and Foster-Fishman (2007), but added focus on the insider’s perspective and the use of multiple data sources and triangulation during analysis:

... intensive, team-based qualitative inquiry with (a) a focus on the insider’s or emic perspective, (b) using multiple sources and triangulation, and (c) using iterative data analysis and additional data collection to quickly develop a preliminary understanding of a situation (2014, p. 3).

Rapid qualitative research has also been defined as empirical research that: lasts up to six months, (or longer if composed of multiple short and intensive stages of data collection and analysis); focuses on documenting aspects of the world through the eyes of others; integrates the subjectivities of the researcher as part of the research process (i.e., reflexivity); and engages with some form of social theory (Flick, 2018; Lapan et al., 2011; Vindrola-Padros, 2021a).

All of these definitions mention the intensive nature and short duration of the research, yet there is disagreement between pioneering authors in relation to what constitutes a study that is rapid in duration. Proposed study timeframes for rapid studies have included:

- A few days (e.g., 4–11 days) (c.f. study examples in Johnson and Vindrola-Padros, 2017)
- 2–4 weeks (but can be as quick as 5 days) (Beebe, 2014)
- 3 weeks (Pearson et al., 1989)
- 4–8 weeks (Long et al., 1988)
- 6 weeks (Scrimshaw et al., 1991)
- 8–12 weeks (Bentley et al., 1988)
- 12 weeks (Handwerker, 2001)
- 6 months (24 weeks) (Vindrola-Padros and Vindrola-Padros, 2018).

It is important to note, however, that study duration needs to be considered loosely as some rapid qualitative studies, particularly rapid evaluations, might have a longer duration, but include sequences of short periods of data collection and analysis and sharing of emerging findings in the form of feedback loops or cycles (McNall et al., 2004; Vindrola-Padros et al., 2021).

Brief overview of rapid qualitative approaches and their history

The origins of anthropology-informed rapid qualitative research involved quick surveys in rural settings in the 1970s, mainly in low- and middle-income countries (LMICs) (Chambers, 1994). They examined the local conditions, health seeking behaviors, and beliefs and attitudes of communities to inform the implementation of social or health interventions—seeking out insider or “emic” perspectives to improve existing programmes or services, or to design more effective and culturally appropriate interventions. The rapid timelines were in response to the short timelines and limited budgetary requirements associated with their work. Many studies employed a range of methods and some studies were guided by structured data collection templates or “field manuals” (e.g., Rapid Assessment Procedures, Rapid Ethnographic Assessments) (Scrimshaw and Hurtado, 1987; Bentley et al., 1988). Researchers often involved community members or people trained in fieldwork research, not only for the local knowledge and research capacity they brought to the team, but also because research teams had a desire to empower the communities they studied (Chambers, 1991).

In parallel to the projects described above, anthropologists also began partnering with multilateral and local government agencies to develop rapid evaluation methods to examine project impacts (McNall and Foster-Fishman, 2007). Other methods were then developed as rapid research moved into urban, high-income country (HIC) settings, in response to crisis issues such as the HIV/AIDS epidemic (Fitch et al., 2000).

This section of the chapter includes a description of commonly used rapid qualitative research approaches—grouped where significant overlap exists. An important point to note is that although these approaches share core features, their uniqueness provide researchers with a range of approaches based on preferences on the level of participation of local community, balance of pre-agreed structure, and whether the research is carried out as a lone researcher or in a team. We have presented this sub-section with an adapted table originally developed by the Rapid Research Evaluation Appraisal Lab (RREAL) team (see Vindrola-Padros, 2021b). **Table 1** is intended to allow researchers to use in combination with **Tables 2** and **3** to easily compare approaches and make choices about which approach would best suit a study’s aims, team structure and methods skills (see **Table 1**).

Rapid evaluations are different from other rapid qualitative approaches because they are specifically designed to assess the impact or document the implementation of specific interventions, services or programmes. While some may appear to have exploratory designs, they can be run as process or outcome evaluations. Three of the most common evaluation approaches include: rapid evaluation methods (REM), rapid feedback evaluation (RFE) and rapid cycle evaluation (RCE) (see **Table 2**) (Vindrola-Padros et al., 2020).

In summary, the rapid methods described vary primarily in relation to their aims, participatory nature, and level of pre-defined structure (vs. exploratory nature). The table below (**Table 3**) provides five continuums through which the methods described above can be better understood.

Five key features of rapid qualitative research

As mentioned above, the field of rapid qualitative research has a wide range of approaches, each with their rich history and unique purpose. Yet despite this variability, many of these approaches have characteristics in common, have been used in combination and have even cross-fertilized to create new types of designs. In our reviews of this field (Johnson and Vindrola-Padros, 2017; Vindrola-Padros and Vindrola-Padros, 2018; Vindrola-Padros et al., 2020), we have been able to identify key characteristics of rapid qualitative research that are shared across most approaches. While the characteristics might also describe some long-form qualitative research designs, they appear to be key features of all rapid research studies, and include:

1. The implementation of scoping studies or preparatory work
2. Reliance on team-based research
3. Carrying out data collection and analysis in parallel
4. Considering different types of analyses for different purposes
5. The development of feedback loops to share emerging findings

Scoping or preparatory stages are rapid explorations of potential study topics to define the scope and finalize the research questions as well as to engage with stakeholders before the study design is finalized. In many cases, the preparatory or scoping work, developed prior to the design of a rapid study, can take longer than the period of data collection. However, this stage is important in rapid qualitative research, as it is used to initially understand the area of study and identify the need for research, decide/refine research questions, identify suitable theoretical perspectives, review existing literature/collect information on the area, identify the best rapid research approach, select methods for data collection and analysis and design the dissemination plan/strategy.

Table 1 Overview of common rapid qualitative research approaches.

<i>Approach</i>	<i>Rapid rural appraisal</i>	<i>Participatory rural appraisal</i>	<i>Rapid ethnographic assessment (REA)</i>	<i>Rapid assessment, response and evaluation (RARE) model</i>	<i>Rapid appraisals and rapid assessment processes</i>	<i>Rapid qualitative inquiry ('team-based assessment')</i>	<i>Rapid ethnographies</i>	<i>Rapid assessment procedures (RAP)</i>
Aims	To diagnose/assess a situation/context. To be pragmatic, cost-effective, accurate and relevant/timely.	To diagnose/assess a situation/context. To lead to change/action and share empowering approaches.	To diagnose/assess local conditions to inform the design of effective interventions by exploring indigenous understandings of health issues.	To diagnose/assess a situation/context. To produce recommendations for interventions appropriate for local culture and area. To complement ongoing processes/monitoring rather than replace them. To determine effectiveness of RARE and the recommended intervention (once implemented). To generate local research capacity.	To diagnose/assess a situation/context. To produce recommendations for interventions appropriate for local culture and area with an emphasis on gaining rich data on insiders' perspectives.	To explore/seek understanding on 'why things are as they are' (helpful in investigating issues that are not yet well defined). To help make preliminary decisions about interventions or changes/additional research or monitoring.	To explore/seek understanding in rapid fieldwork periods.	To assess and evaluate programmes. To improve health program planning and evaluation by capturing the social and cultural factors that frame health behaviors. To empower community members.
Origins	Late 1970s, early 1980s in LMICs in agriculture/environmental studies.	1990s adaptation to RRA (also drawing on activist participatory research) with more community participation, covering studies in natural resources management, agriculture, poverty and social programmes, and health and food security in LMICs.	Late 1980s with a focus on public health in LMIC.	Late 1990s/early 2000s with a focus on health crises in the US.	Draws on REAs, ethnographic and case study research, action research and PAR. Developed in LMIC settings.	Child' method of RAP but framed within "systems thinking". Examples span disciplines and industries (e.g., agriculture, education, health). Originally based in LMICs but now being used to inform policy in many different settings.	Long-form ethnography (see Wall, 2014 ; Knoblauch 2005).	1980s in LMICs, driven by time constraints and the high costs associated with long-term evaluation.

Team	High-level of expertise and research skills. Community members involved in analysis and dissemination only.	Locals collect data (and researchers participate in community life).	Depends on individuals familiar with the local culture/area to act as researchers.	Ethnographer-led team including local working groups (e.g., local government or health agencies) with no previous research). Working groups trained and play a central role in the design and implementation of the study by reviewing available local data (surveillance, epidemiological, planning data, GIS maps) and identifying areas or at-risk groups.	Intensive teamwork, including members of the community/local development agencies as part of the team.	Team members (2–5) should be from different disciplines to contribute their own perceptions/theories to generate different ways of collecting/interpreting data. Insiders involved where appropriate.	Carried out by lone researchers or teams.	Multi-disciplinary research team including at least one member from the cultural group of interest (with no research experience required) who all design and implement studies. Development of materials to train team members.
Methods	Range of qualitative methods. Emphasis on making use of existing data.	Semi-structured interviews, group interviews, oral histories, transect walks, mapping and modeling of local conditions, timelines and trend change analysis, and seasonal calendars. Sources include secondary sources, key informants, local residents, and observations.	Defining characteristic is the structured field guide to suggesting the type of information required. More limited range of methods than PRAs and RAs, but multi-staged complementing open-ended approach.	RARE studies are often proposed by the community/area where the study will take place. Combines focus groups, key informant interviews, observations, mapping and rapid 'street intercept' assessment interviews. Uses RARE manuals and procedures adapted to context/topic. Findings feedback throughout. Findings are also shared regularly with key stakeholders throughout the project.	Used to collect data from key contacts or informants in the communities. Interview data are combined with focus groups, community walks and mapping, and surveys. When possible, existing data are used. Iterative data collection and analysis. Triangulation happens through research team interaction during analysis.	Relaxed, semi-structured interviewing (no formal questions written out) that encourages insiders storytelling. Sample focused on the poorer, less articulate, more upset, and those least like the members of the RQI team. Team interviewing used (i.e., at least two team members present at each interview). The interaction of team members captures different aspects of conversations, leading to triangulation of findings, and adds layers of interpretation to the research process. Data analyzed as researchers collect data, allowing near real-time sharing of findings/discovery of gaps before the fieldwork was over.	Similar to long-form ethnographic research (e.g., interviews, observations and documentary analysis).	RAP manual is crucial in guiding researchers without a background in disease-based research skills or qualitative research. Use several data collection methods to verify information through triangulation. Iterative data collection and analysis to facilitate continuous adjustment.

Table 2 Types of rapid evaluation.

	<i>Rapid evaluation methods</i>	<i>Rapid feedback evaluation</i>	<i>Rapid cycle evaluation</i>
Aims & Origins	Aims: to evaluate and identify operational problems within a program/project and take action. Origins: developed by the World Health Organization to assess quality of health care services, identify operational problems, and assisting managers in taking corrective action.	Aims: to evaluate program/project/system and provide program managers with focused, timely evaluation conclusions. Origins: based on Joseph Wholey's experiences as an evaluator working with US federal program managers and his awareness of clients' needs for the timely delivery of findings to inform key programming decisions (McNall and Foster-Fishman, 2007).	Aims: to evaluate program/project/system, providing timely feedback to funding organization, program staff and care providers. To offer support for continuous quality improvement. Origins: influenced by PDSA cycles used in quality improvement.
Methods	Team: core team involving local community who design and implement evaluation. Active involvement and participation of all stakeholders (to increase engagement and use of findings). Methods: typically mixed-methods. Observation and survey-based diagnostic activities.	Team: team-based. Methods: quantitative or mixed methods. Data are continually collected (e.g., interviews, existing data), analyzed and used to inform action within a short time period.	Team: stable team (to ensure access and build relationships with sites). Methods: quantitative, qualitative or mixed methods.

Table 3 Questions guiding the selection of rapid qualitative approach.

<i>Questions to guide study design</i>	<i>Types of rapid qualitative research approaches</i>		
What is the aim of the study?	Diagnostic purposes: rapid appraisal, RRA	Exploration or to seek understanding: rapid ethnography, RQI	Evaluation: rapid evaluations, RAP
How participatory?	High degree of participation: PRA, RARE	Medium degree of participation: rapid appraisal, RQI	Low degree of participation: rapid ethnography, rapid evaluations
How structured?	Structured: RAP, REA	Somewhat structured: rapid evaluations, rapid appraisals, RQI, RRA, PRA	Unstructured: rapid ethnographies
Team or lone researcher?	Team-based: rapid appraisals, RQI, RARE, RAP, team-based rapid ethnographies		Lone researcher: rapid ethnographies and some types of rapid evaluations
When are findings needed? (one time-point or regular feedback?)	Regular feedback: rapid feedback or rapid cycle evaluations, rapid appraisals, RAP, RARE, rapid ethnographies		One-time feedback: REM, rapid ethnographies

Adapted from RREAL's Rapid qualitative research decision tool (available at <https://www.rapidresearchandevaluation.com/resources>).

Most of the rapid qualitative research approaches described above, except perhaps rapid ethnographies, rely on the use of teams of researchers. In the case of some approaches, such as RAPs, teams of field researchers are used to cover more ground, that is, carrying out more observations, interviews or visits to communities when compared to research carried out by individual researchers. Rapid appraisals and rapid qualitative inquiry conceptualize team-based research in a slightly different way, recognizing the importance of teams of researchers from different disciplines, and with levels of expertise and types of knowledge (including insiders and outsiders in community-based research). These teams carry out data collection together, including interviews and observations, and each member of the team contributes a different perspective to data collection and analysis, generating additional layers of insight or interpretation.

Data collection and analysis are seen as stages that need to be carried out in parallel. Thus, analysis begins with the first observation, interview or focus group and data are summarized on an ongoing basis. The summaries of findings in real-time mean that

these can be shared with stakeholders in a timely way. Some analyses can be focused on generating a high-level synthesis of findings if these are required quickly, but some rapid studies have also relied on more in-depth analysis, where researchers have more time to develop fuller data sets, engage with more complex theoretical frameworks and provide deeper insight into the findings. The type of analytical approach was selected based on the purpose of the analysis, whether this is to share findings that can be actioned quickly, inform the design of future studies, or make a contribution to academic research.

The type of data collected or analysis undertaken in rapid research is iteratively changing based on responses from stakeholders during project team feedback. While the main purpose of feedback loops is to share emerging findings so these can be used to inform decision-making processes, feedback from stakeholders can also be used to make changes in the study design. For instance, addressing areas that might have been missed or expanding the sampling framework to include additional points of view.

The challenges of rapid qualitative research

Delivering timely and actionable findings through implementation of rapid qualitative approaches remains a challenge and continues to lag behind the needs of evidence-based decision making (Glasgow et al., 2014; Riley et al., 2013; Vindrola-Padros et al., 2020, 2021). This section explores some of the challenges associated with rapid qualitative research which may account for this, and signposts to empirical as well as methodological papers that discuss the solutions and trade-offs.

Overcoming assumptions

One of the main challenges faced by researchers using rapid qualitative methods is overcoming the assumption that rapid research lacks rigor (Pink and Morgan, 2013; Vindrola-Padros, 2021a). Some authors warn against rapid methods for mainstream use (e.g., Fitch et al., 2000), while others warn of poor validity (e.g., Utarini et al., 2001). Alternatively, other research groups acknowledge these challenges but instead seek to develop strategies to overcome them, viewing implementation as the limitation rather than the study duration itself (Vindrola-Padros et al., 2020).

There is a need to distinguish between “rapid” and “rushed” research, rapid does not inherently make for a rushed or poorly implemented study (Beebe, 2005; Fitch et al., 2000; Manderson and Aaby, 1992; Vindrola-Padros, 2021a). As put by Robert Chambers, rapid approaches could be “... too over-sold, too rapidly adopted, badly done, and then discredited, to suffer an undeserved, premature burial as has occurred with other innovative research approaches” (Chambers, 1991). Unfortunately, these assumptions can influence how findings are viewed and used in practice, irrespective of the quality of their design and implementation (McNall and Foster-Fisher, 2007).

Theoretical grounding and reflexivity

Maintaining theoretical grounding during rapid qualitative research can be challenging due to time pressures and the applied nature of the research aims (Vindrola-Padros, 2021a; Vindrola-Padros and Johnson, 2020; Vougioukalou et al., 2019). This has resulted in some authors arguing that rapid qualitative research is atheoretical and lacks a critical angle (Cupit et al., 2018; Manderson and Aaby, 1992). However, there are many instances where knowledge can be produced in rapid timeframes which have strong theoretical roots (Pink and Morgan, 2013; Vindrola-Padros and Johnson, 2017).

Similarly, a recent review of rapid ethnographies revealed that not enough attention is paid by researchers to reflexivity, this being the authors’ critical analysis of their own epistemological influences, which interact with the production of knowledge and the ways in which the researcher’s presence might alter the practices being observed (Vindrola-Padros and Vindrola-Padros, 2018; Vindrola-Padros, 2021a). This has been reported in relation to team-based approaches, as typical of rapid qualitative research (Hesse-Biber, 2016; MacQueen and Guest, 2008). While this represents a significant limitation, it is one which is not limited to rapid research and reflects pitfalls in execution rather than an inherent limitation of the methods of rapid qualitative research (Vindrola-Padros, 2021a,b). For instance, a team-based reflexivity model has been developed and tested in groups undertaking rapid qualitative research (Rankl et al., 2021).

Breadth versus depth

Breadth and depth pose a challenge in rapid qualitative research, as it is not always feasible to capture all of the relevant social, cultural, political, or economic factors at hand, or to engage with all contradictions (Vindrola-Padros, 2021a,b; Bentley et al., 1988; Manderson and Aaby, 1992b). Scope, therefore, is a key factor to take into consideration. To prioritize the areas of study, a number of techniques (e.g., scoping studies) in rapid qualitative research have been developed to ensure the most salient issues are captured and, within reason, incorporate varied views (Vindrola-Padros, 2021a,b).

Sampling and rapport

Sampling strategies in rapid qualitative research could represent a challenge. Time constraints may mean that the sample reflects those most willing to engage with research and omits those with alternative views, or that sample sizes are small (Vindrola-

Padros and Vindrola-Padros, 2017). This said, reviews have found rapid research to justify sampling strategies and to seek some degree of representativeness (Vindrola-Padros and Vindrola-Padros, 2017). While a challenge, sampling in rapid qualitative research can capture a wide range of views through careful selection of study participants and implementation of sampling guides which set targets for the recruitment of key groups (Beebe, 2014; Handwerker, 2001).

Another challenge, due to the short duration of fieldwork, may include developing in-depth rapport with study participants. This said, just because a study is rapid does not mean that exposure to individuals may be less, as similar durations of contact may be similar at an increased intensity (Pink and Morgan, 2013). Where this is not the case, while time does of course contribute to the formation of strong relationships, relationships also stem from the researcher's ability to foster rapport independent of duration. Furthermore, rapport can be integrated into rapid qualitative research from pre-existing relationships, previous studies, or times outside of data collection periods (Vindrola-Padros, 2020).

Team-based fieldwork and analysis

Rapid qualitative research frequently demands the set-up of research teams in order to facilitate shorter research timeframes (Vindrola-Padros et al., 2020; Beebe, 2014; Brown et al., 2008). This can be challenging due to the various backgrounds within a research team, creating a collaborative working environment, and maintaining communication across a number of actors (Barry et al., 1999; Bikker et al., 2017). Furthermore, team-based approaches can delay research findings due to challenges with varying levels of experience, training needs, maintaining consistency, exploring everyone's perspectives, reaching consensus, collaborative writing, and settling authorship disagreements (Rankl et al., 2021).

While team dynamics in rapid qualitative research present several challenges, there is benefit in combined knowledge bases for improving rigor of data collection and analysis through the strength of collective interpretation (Rankl et al., 2021; Barry et al., 1999; Beebe, 2001, 2014; Armstrong and Lowndes, 2018). Furthermore, limitations can be problem-solved, such as maintaining consistency through the use of standardized tools (e.g., RREAL Sheets—previously referred to in publications as RAP sheets) (Bikker et al., 2017; Rankl et al., 2021).

Funding

Rapid qualitative research teams receiving funding per project may have challenges maintaining staff with full-time contracts. Hence, teams may have to combine rapid projects with long-term studies or conduct multiple rapid studies simultaneously in order to cover percentages of full-time employment or part-time contracts. Other, more traditional, means of obtaining funding via academic channels or grants may be possible, but rapid research teams will most likely use hybrid funding models where funding is sought from a number of options, including private consultancies.

Ethics and governance

Delays can often be produced by review of studies by research ethics committees (Driscoll et al., 2008; Iedema et al., 2012; Polito et al., 2014; Vindrola-Padros, 2021a). Reported challenges already exist in relation to qualitative research more broadly, but rapid qualitative research faces further challenges as an uncommon type of design which can result in misunderstandings and produce further delays with gaining approvals. Despite the implementation of a number of fast-track processes, ethical review continues to delay the set-up of rapid studies and deter research teams from engaging with rapid qualitative methods (Vindrola-Padros, 2021a).

In part, delays in gaining ethical approvals may be due to the deemed intrusiveness or burden for research participants, whether they be patients, healthcare workers, public health authorities or members of the public (Vindrola-Padros et al., 2020). While it is important to consider whether research should be carried out at a particular time and potential burden or harm, it could also be unethical not to carry out research and miss immediate, actionable data which could inform response efforts and preparedness strategies (Vindrola-Padros et al., 2020). Furthermore, steps can be taken to reduce burden (flexible interviewing times and shorted durations) and participants have reported that, despite burden, taking part in interviews can be a helpful, even therapeutic, process (Vindrola-Padros et al., 2020).

The future of rapid qualitative research

The rich history of rapid qualitative research spans decades, a period of time during which researchers have undertaken both methodological experimentation and adaptation, as well as reflected on their learning through various journal articles and practical handbooks. Standing back from the various methodological approaches, it is clear that the aims and approaches to data collection and analysis have been and continue to be combined or undergo cross-fertilization. Most of the adaptations to methodologies have been iterative, sometimes developed by the same authors as they refine their thinking and other times by other researchers who adapt methodologies to their own study design or to new disciplines or contexts resulting in a slightly different approach.

As the field of rapid qualitative research moves forward, it is important to recognize the changing nature of practice. New approaches are being produced regularly and this will continue to happen over time. This section includes a description of some of the emerging methods in healthcare and education, as well as other research areas.

New approaches to rapid qualitative research

In recent years, there has been significant experimentation among rapid ethnographies, which has involved combining elements from different rapid research approaches. These new developments or spin-offs include:

- *Focused rapid ethnographic evaluation (FREE)*: this is a modification of the focused ethnography approach and it involves the extensive use of fieldnotes instead of digital recordings (Patmon et al., 2016). FREE can be useful for analyzing human-computer interactions and the assessment of emerging technologies in the workplace (Patmon et al., 2016).
- *Short-term focused video ethnographic case study*: this approach combines video footage, observational field notes, and “video-cued” interviews to provide in-depth analysis of one case study or situation. Harte et al. (2016) have used it to explore the hospital design factors influencing childbirth supporters’ experiences.
- *RAPICE*: the Rapid Assessment Procedure Informed Clinical Ethnography (RAPICE) was developed in the field of clinical trials (Palinkas and Zatzick, 2019) to collect and use qualitative data to understand trial implementation processes and address barriers to recruitment and other issues. It combines some of the characteristics of RAPs (and other rapid qualitative methods that aim to assess and evaluate) with intensive participant observation normally used in clinical ethnography (Zatzick et al., 2011). Study findings are shared regularly with the trial team to inform changes in trial delivery (Palinkas and Zatzick, 2019).
- *Rapid fieldwork approach*: following trends in human-centered computing (HCC) to optimize the design and implementation of technology, Eden et al. (2019) propose the use of multiple focused field trips to sensitize research teams to the needs of stakeholders—however this is often done using extremely compressed timeframes of one to two-day field trips where researchers spend 2–4 h with participants (Eden et al., 2019).

Conclusions

In summary, “rapid qualitative research” is an umbrella term analogous to “long-form qualitative research”, with many approaches emerging over time. Rapid and long-form qualitative research have many common characteristics; however, rapid qualitative research approaches are unique because they near-unanimously rely on: a scoping phase of work, teams of researchers (rather than lone researcher designs), researchers carrying out data collection and analysis in parallel, implementing rapid techniques during analysis, and sharing emerging findings using regular feedback loops. The strengths of rapid qualitative research approaches are that they allow research teams to undertake meaningful qualitative research on short timelines, often for a smaller budget than traditional long-form qualitative research. On the other hand, the challenges of rapid qualitative research include overcoming the assumption that its approaches lack rigor and do not engage with theory, recognizing that the scope and pace of work will likely mean that it will not be possible to capture all of the relevant social, cultural, political factors at hand, and maintaining theoretical grounding despite the time pressures and the applied nature of the research aims.

In producing new rapid qualitative research, it is important to continue to acknowledge the historical roots of approaches, map where innovations are made and learn from these experiences. As Vindrola-Padros et al. (2021) argues,

if we disregard the rich history of rapid qualitative research, we risk making the same mistakes over and over and not learning from lessons already available in the literature. We also run the risk of applying these approaches in unintended ways, diminishing their engagement with theory, increasing their level of instrumentality and severing their ties with traditions in the social sciences. The future development of the field of rapid qualitative research will depend on our efforts to improve these approaches without losing sight of their history.

Vindrola-Padros (2021a,b).

It will also be important that researchers make explicit how theory and theoretical approaches from different disciplines have shaped all stages of research. Where further elicitation of these details is required, methods-focused papers or appendices to accompany the main findings of an academic paper will help explain the research.

Another outlined assumption is that rapid qualitative research is unable to engage with reflexivity, that is, the “researcher’s critical account of their ‘self-location’ (gender, class, ethnicity, and so on), interests, pre-assumptions and life experiences and how these shape their relationships with study participants and the research process itself” (Vindrola-Padros and Vindrola-Padros, 2018). Many publications reporting findings from rapid qualitative studies have not integrated this critical reflection into the text, but

as with issues related to theoretical engagement, there is no reason why time pressures should prevent researchers from considering reflexivity as an integral part of the research process (Vindrola-Padros, 2021a,b) and some potential models for doing this have already been published (Rankl et al., 2021).

Introduction—quality is complicated

Qualitative scholars have long debated notions of quality within qualitative research, rarely arriving at a conclusive consensus. In fact, [Onwuegbuzie and Leech \(2005\)](#) reviewed literature and found that there were over 50 terms (such as authenticity, trustworthiness, and transparency, among others) used across qualitative publications at that time. We estimate that this list has grown, and were they to repeat their study, they would likely find even more. While this lack of consensus makes writing a chapter such as this daunting, it is imperative that we engage in these conversations in order to continually improve the craft of inquiry as well as our understanding of how scholars enact various forms of quality within qualitative research.

[Corbin and Strauss \(2008\)](#) summarized the uncertainty around describing *quality* within qualitative research that often leaves both new and established researchers feeling mentally debilitated, saying,

I feel paralyzed, unsure of where to begin, or what to write. As I search the literature, I find that evaluation is necessary but there is little consensus about what that evaluation should consist of. Are we judging for 'validity' or would it be better to use terms like 'rigor' ... 'trustworthiness' ... or 'goodness' ... or something called 'integrity' ... when referring to qualitative evaluation? (p. 297).

This lack of consensus can be traced back to earlier qualitative work as well. For example, many of our foundational scholars argued that the concept of *validity*, stemming from epistemological frameworks primarily found in quantitative traditions, is incompatible with values held by qualitative researchers (Kvale, 1995; Lather, 1993; Ravitch and Carl, 2019; Wolcott, 1990). Lather (1993), however, chose to specifically embrace the term *validity* in order to “both circulate and break with the signs that code it ... all of the baggage that it carries plus, in a doubled-movement, what it means to rupture validity as a regime of truth, to displace its historical inscription” (p. 674). Lather’s reclamation of the term validity marked a turning point in how many qualitative scholars conceptualize quality within their research.

Other scholars argue that there are three key concerns that prevent us from being able to present a unified framework for quality in qualitative research: (1) there is little consensus about what quality research looks like, (2) traditional positivist evaluation criteria, such as notions of validity and reliability within quantitative methods, continue to impact the way that we discuss quality in other methodological approaches, and (3) there are very specific culturally- and politically-defined notions about what constitutes as evidence (Cho and Trent, 2020; Trainor and Graue, 2013). These three complications can help us begin to explain why conversations around quality in qualitative research are complicated.

The factors that constitute good qualitative research are interpretable, mutable, and up for negotiation. These quality indicators should be engaged and critically examined; we encourage qualitative researchers to work within this more flexible framework of quality instead of seeking to uphold foundational traditions stemming from other methodological paradigms. Critically engaging with quality determinants turns our focus away from defining good research as the precise application of methods, as more traditionally used in quantitative methods, and instead toward process and outcomes from our work. However, our focus on process and outcomes does not mean that there are no criteria for determining the quality of qualitative methods—there certainly are!

The indicators of quality criteria that you ultimately choose will depend on your theoretical, ontological, epistemological, and methodological decisions and commitments. Ontological and epistemological commitments are particularly important to consider within qualitative research, as researchers will often choose to pursue quality indicators that fit within their beliefs. In other words, what you consider to be good, rigorous, and valid research stems from your assumptions about how knowledge is produced. For more information about how ontological, epistemological, and methodological considerations fit together and for an exploration of some frequently used paradigms, please see other chapters within this encyclopedia provided by Eileen Boswell and Wayne Babchuk (“Philosophical and Theoretical Underpinnings of Qualitative Research”) and Peggy Shannon-Baker (“Philosophical Underpinnings of Mixed Methods Research in Education”).

Within the following sections, we introduce the concept of what we call The Salad Bar Approach, detail 23 quality determinants that are often used across qualitative scholarship, and finally, summarize the chapter with an included demonstration of how some of the quality determinants can be used.

The salad bar approach to considering quality in qualitative research

You have a variety of choices when it comes to choosing which quality determinants to use within your qualitative project. In fact, there are arguments being made for new determinants all the time! It would be impossible to list and define every single existing quality construct due to practical concerns, such as page limitations, and timeliness concerns, as there are consistently new arguments taking place about what does/does not and should/should not exist in regard to measuring quality. Instead, we wish to share a metaphor that one of our authors, Leia, provides to students within her qualitative methodology courses: the salad bar approach.

Imagine that you are building a salad and that all of the available ingredients, toppings, and salad dressings are spread upon a table before you. You build your salad based on how you, personally, enjoy it; perhaps you include a fair amount of lettuce, a large number of other vegetables, such as zucchini, cucumbers, and carrots, a light sprinkling of cheese, and finally, a touch of ranch dressing. Another person walks up to the table where these ingredients are presented and builds their salad: a few handfuls of arugula, many onions, sunflower seeds, tomatoes, and a massive heaping of raspberry vinaigrette. While your salads differ in how you built them, they are both quality salads. If asked to describe how each ingredient decision was made, you would both be able to justify what you believe to contribute to a good salad.

Qualitative research is very much the same as these salads. Each qualitative researcher may work through the inquiry process in different ways, utilize diverse theoretical frameworks and paradigmatic beliefs, engage in various forms of data collection and analysis, and apply different forms of quality evidence. The most important thing to consider when judging each of these qualitative salads is to justify your composition. While it is often known that authors must provide a justification for readers as to how each action was taken throughout the research process fits their research question, it is less common knowledge that you are

also able to choose and should therefore justify which quality determinants best fit your theoretical, ontological, epistemological, and methodological commitments.

There are few limits across diverse representations of qualitative research—and this discussion of quality is no different. There are many types of quality determinants that you may choose to use in your qualitative work—you must simply ensure that you have justified your decisions and that they fit with the other elements of your study.

Determinants of quality in qualitative research

In this section, we present 23 determinants of quality in qualitative research. We define each construct and provide reflective questions for researchers seeking to utilize each particular determinant. We have also created [Table 1](#), which lists the quality determinants, key citations for each, similarly used terms, and paradigms with which each determinant is commonly paired. Again, we wish to reiterate that there is little consensus within the broad field of qualitative methodologies. We cannot impress upon you enough the vast importance of knowing what is valued within your field, as some of these constructs are more common and accepted than others within individual fields. Our entries, below, have been alphabetized for ease of locating specific determinants.

Authenticity

Scholars who seek authenticity are concerned with both engaging in a worthy topic and understanding the larger implications of their research (i.e. how the project potentially benefits society). [Guba and Lincoln \(1989\)](#) described five dimensions of authenticity: (1) fairness related to the research participants and stakeholders, (2) ontological authenticity, which refers to the alignment between the researcher's paradigmatic approach, (3) educative authenticity, meant to increase the audience's awareness of the issue, (4) catalytic authenticity, which refers to the study's potential for action, and (5) tactical authenticity, referring to change or empowerment as a result of the research project.

When considering fairness, it may be helpful to ask yourself:

- Am I doing what is in the best interest of my research project, my research participants, and the stakeholders?

When considering ontological authenticity, it may be helpful to ask yourself:

- Am I being authentic to my paradigmatic views?
- Am I appropriately employing my paradigms?

When considering educative authenticity, it may be helpful to ask yourself:

- Am I educating my readers clearly and accurately?

When considering catalytic and tactic authenticity, it may be helpful to ask yourself:

- What can my work catalyze people to do?

Centering ethical considerations

Qualitative scholars have long argued for emphasizing ethical considerations within your writing. You should consider the procedures you're using, participant well-being or burden, demonstrate cultural competency, respect relationships, and maintain other ethical boundaries set in place by the nature of the research study. [Miles et al. \(2019\)](#) posited that centering ethics allows research to come out of a place of respect, dignity, and honor to the research process and its participants. It is each researcher's responsibility to uphold ethical guidelines set by institutional review boards and other research governing bodies, yet the concept of centering ethical considerations calls for engagement in ethical thinking outside of the bounds set by those gatekeepers. Additionally, it is the researcher's responsibility to anticipate any ethically challenging situations that could arise throughout the research process and have contingency plans in place. One must remember to maintain ethics throughout project conception, data collection, analysis, and reporting results. These considerations should then be detailed within publications so that readers can understand the ethical thinking that the author(s) engaged in. When ethical considerations are clearly delineated within your work, you are able to bring attention to ethical decision-making throughout the study. It is your responsibility to report adverse events and consider these events in reviewing the conclusion of the study.

When considering centering ethical considerations, it may be helpful to ask yourself:

- What ethical concerns may arise during my study in regard to interacting with participants?
- What are the best ways for me to handle sensitive information shared with me by the participants?
- What steps should I take when working with protected or vulnerable populations (e.g., children, employees, incarcerated individuals)?
- How can I ensure that all members of my research team are on the same page regarding ethical decision-making?

<i>Quality determinant (key citations)</i>	<i>Brief description</i>	<i>Similar terms</i>	<i>Common paradigms</i>
3.1 Authenticity (Lincoln and Guba, 1985)	Researchers must engage in a worthy topic and understanding the larger implications of their research.	N/A	Constructivism Interpretivism
3.2 Centering ethical considerations (Miles et al., 2019; Tracy, 2010)	Researchers must emphasize ethical decision-making within their work.	N/A	Critical paradigms Interpretivism Postpositivism
3.3 Consistency (Drisko, 1997; Lincoln and Guba, 1985; Reid, 1994)	Researchers must understand the literature that contextualizes their study and provide explicit connections between the literature and their findings.	• Confirmability (Johnson et al., 2020) • Dependability (Nassaji, 2020) • Reliability (Yilmaz, 2013)	Postpositivism
3.4 Credibility (Lincoln and Guba, 1985; Patton, 1999; Tracy, 2010)	Researchers must provide enough evidence to demonstrate that their interpretations of the data are meaningful.	• Internal validity (Meijer et al., 2002) • Trustworthiness (Little and Green, 2022)	Interpretivism Postpositivism
3.5 Critical subjectivity (Lincoln, 1995)	Researchers must deconstruct their beliefs, biases, subjectivities, experiences, identities, and more, to understand how their core beliefs affect their decisions throughout the study.	• Transformative subjectivity (Frieden, 1989)	Constructivism Critical paradigms Interpretivism
3.6 Meaningful coherence (Lather, 1993; Tracy, 2010)	Researchers must ensure that their research reports demonstrate significant alignment through their introduction, literature review, methodology, results, and discussion sections.	N/A	Interpretivism Postpositivism
3.7 Member checking (Lather, 1986; Lincoln and Guba, 1985)	Researchers must share their findings with participants in order to confirm the accuracy of their interpretation.	• Member reflections (Tracy, 2010)	Constructivism Critical paradigms Interpretivism Postpositivism
3.8 Memoing (Glaser, 1978)	Researchers must keep a record of their thoughts, feelings, emotional responses, and questions that arise throughout the inquiry process.	N/A	Interpretivism Postpositivism
3.9 Positionality (Lincoln, 1995)	Researchers must reflect on their identities in relation to their study's participants and data.	• Standpoint judgment (Nakata, 2015)	Constructivism Critical paradigms Interpretivism
3.10 Reciprocity (Lincoln, 1995; McLaughlin and Tierney, 1993)	Researchers must consider the bonds that exist between researcher and participant and work to create a relationship marked by trust, care, and mutual benefit.	N/A	Constructivist Critical paradigms Interpretivist
3.11 Reflexivity (Peshkin, 1988)	Researchers must reflect upon their paradigmatic commitments, their relationship to the study participants, and their beliefs about the research topic.	• Critical reflexivity (Glass, 2015) • Transformative reflexivity (Relano Pastor, 2011)	Constructivism Critical paradigms Interpretivism Postmodernism
3.12 Relational ethics (Adams et al., 2015)	Researchers must recognize and protect the connection between themselves, their participants, and the communities in which they live and work.	N/A	Constructivism Critical paradigms
3.13 Resonance (Schutz, 1967; Tracy, 2010)	Researchers must influence readers through evocative representations of their data.	N/A	Constructivism Interpretivism
3.14 Rich rigor (Golafshani, 2003; Tracy, 2010)	Researchers must provide a detailed, clear research design and methodology.	N/A	Interpretivism Postpositivism
3.15 Sacredness (Lincoln, 1995; Schaef, 1981)	Researchers must have a profound respect for human dignity and justice, and seek to turn their findings into action.	N/A	Constructivism Critical paradigms Feminism Interpretivism

Table 1 Table of quality determinants.—cont'd

<i>Quality determinant (key citations)</i>	<i>Brief description</i>	<i>Similar terms</i>	<i>Common paradigms</i>
3.16 Sharing privilege (Lather, 1993; Lincoln, 1995)	Researchers must examine how they can share with participants and communities the earned dignity, respect, prestige, and economic benefits from publishing their work.	N/A	Constructivism Critical paradigms Feminism Interpretivism
3.17 Significant contributions (Schwandt, 1996; Tracy, 1995)	Researchers must use their research to address theoretical, methodological, cultural, moral, and practical gaps within the literature.	N/A	Critical paradigms Postpositivism
3.18 Sincerity (Emerson et al., 1995; Seale, 1999)	Researchers must be transparent about the decisions made throughout their research.	N/A	Constructivism Interpretivism
3.19 Sites as arbiters of quality (Lincoln, 1995; Savage, 1988)	Researchers must pursue a situated and complex knowledge that embraces ways of knowing beyond their own in order to assist marginalized populations.	• Communitarian (Denzin, 2006) • Community as arbiter of quality (Boughton, 1997)	Constructivism Critical paradigms Interpretivism
3.20 Transgressive validities [ironic, rhizomatic, paralogical, and voluptuous validity] (Lather, 1993)	Researchers must reject traditional positivist conceptualizations of validity in order to proliferate form (ironic validity), understand how their participants exist within systemic networks (rhizomatic validity), foster differences and embrace contradictions (paralogical validity), and obtaining an abundance of data (voluptuous validity).	N/A	Feminism Postmodernism Poststructuralism
3.21 Triangulation (Denzin, 1978)	Researchers must utilize multiple data sources to obtain answers to their research question(s).	N/A	Constructivism Interpretivism Postpositivism
3.22 Voice (LeCompte, 1993; Lincoln, 1995)	Researchers must consider whose voice(s) are undervalued, and seek out those who are silenced within data collection.	• Polyvocality (Clifford, 1986)	Constructivist Critical theorist Interpretivist
3.23 Worthy topic (Guba and Lincoln, 1989; Tracy, 2010)	Researchers must choose topics that are significant to current literature, society, and personal events.	N/A	Postpositivist

Consistency

Scholars who choose to pursue consistency argue the importance of understanding the literature contextualizing your topic and sharing with readers a fluid story about those connections through the presentation of your findings. These scholars seek to make connections throughout the study's report, always linking back to the research purpose, as the purpose should drive all decisions that they make throughout the inquiry process (Noble and Smith, 2015; Lincoln and Guba, 1985), and ensure that they provide a rationale for these decisions that aligns with their research purpose. Further, Drisko (1997) suggested feedback sessions with the participants to confirm your interpretation of their data and the conclusions that you have drawn; this process is often referred to as member checking (described later in this list). It is critical to avoid being vague, leaving readers with too much of an opportunity to draw conclusions of their own. As the researcher, you are privy to the originally collected data and have the best sense (second to your participants!) of what to include in order to descriptively share findings with readers.

When considering consistency, it may be helpful to ask yourself:

- Are my research questions strong?
- Does each section within my writeup refer back to the purpose of my study?
- Do I make explicit connections between my research questions, the literature, my methodological decisions, and my findings?
- Does this clearly connect to the purpose of the study?
 - If your answer is "no," or unclear, you should approach your project in another way in order to maintain consistent alignment throughout the report.
 - If the answer is "yes," have a colleague read over your work to check for the consistency you aimed to maintain throughout the paper.

Credibility

Readers of qualitative research should trust your findings are credible. Credibility refers to your ability to use your data as proof of findings (Patton, 1999). When a researcher is credible, they present enough evidence regarding the data they have collected, analyzed, and shared to draw their conclusion. Researchers must carefully extrapolate pieces of data that best represent their conclusions while maintaining the nature of the participants' words. It is critical that the researcher draws conclusions from the data and *shows* rather than *tells* the readers how those conclusions were made, and that those conclusions are believable to the reader based on the evidence presented (Tracy, 1995).

To increase the credibility of your conclusions, participate in data-checking techniques such as triangulation, member checking, polyvocality, and reflexivity (see Tracy, 1995), which are detailed in this chapter. A common theme among these techniques is including your participants in the process of drawing conclusions based on the data. Once you have made conclusions about your findings, take time to ensure that (1) the information you shared was representative of participant experiences, (2) you included multiple voices throughout your findings (when appropriate), and (3) you have addressed various levels of relationship power dynamics. Further, you should indicate which credibility techniques you used to help your readers understand the quality of your findings.

When considering credibility, it may be helpful to ask yourself:

- Have I participated in one or more data-checking techniques?
- Have I described these techniques in my written report?

Critical subjectivity

Critical subjectivity involves the process of reflexively deconstructing our own beliefs, biases, subjectivities, experiences, identities, and more, in order to understand our core beliefs and then share those beliefs with our readers. Lincoln (1995) argued that "such reflexivity or subjectivity enables the researcher to begin to uncover dialectic relationships, array and discuss contradictions within the stories being recorded, and move with research participants toward action" (p. 283). It is important to understand not only the beliefs, experiences, and perspectives that each of us brings to our research but also how those beliefs affect our actions throughout the inquiry process.

In order to participate in critical subjectivity, you must first critically examine the lenses that you bring to a study. As mentioned above, these should include your own beliefs, biases, subjectivities, experiences, identities, and anything else relevant to the topic that you are studying. You should engage with this practice throughout the inquiry process, and include these considerations within your final written research report so that readers can understand your process and understand how you approached the study.

When considering critical subjectivity, it may be helpful to ask yourself:

- How do your beliefs about the creation of knowledge impact the way that you design your study?
- Which forms of evidence do you feel are worthy?
- How may your shared and unshared identities affect the way that you interact with participants?
- How may your beliefs affect the way that you analyze the data, and even which findings seem to jump off of the page to you?
- How might your lived experience shroud other findings from your immediate view?

Meaningful coherence

Scholars who wish to claim meaningful coherence should ensure that their research reports demonstrate significant alignment throughout the introduction, literature review, methodology, results, and discussion sections (Tracy, 2010). More specifically, authors should confirm that (1) there is a clear purpose statement at the onset of the research paper and that the research study achieves that stated purpose, (2) the literature review provides context and informs the research questions, (3) the methods address the stated research question(s) and are grounded in appropriate theoretical and paradigmatic approaches, and (4) the discussion section speaks to and addresses concerns brought to light in the literature review. Ultimately, a research study that is meaningfully coherent achieves the stated purpose and leaves readers feeling fulfilled in the pursuit of that purpose.

When considering meaningful coherence, it may be helpful to ask yourself:

- Have I ensured that I tell a single, cogent story of my study from beginning to end?
- Have I considered how other scholars from the existing literature may impact how I frame my study?
- Have I chosen a methodology that is best suited to answer my research questions?
- Are my research questions grounded in my theoretical and paradigmatic commitments?

Member checking

Researchers who choose to utilize member checking most often tend to share their findings with participants in order to determine "whether the participants recognize them as true or accurate" (Lindlof and Taylor, 2002, p. 242). This can be an incredibly useful

process, as participating in member checking can serve not only as validation of your interpretations, but also as new data or points of view by which to view your study (Tracy, 2010). This process also allows us to share power with the participants by allowing them to control how their stories are presented. We often participate in member checking by sending participants two files; (1) one with the full written findings section, so that they may see their data within the overall context of the study, and (2) another with just their portions pulled out in case that is easier for the participant to interact with.

When considering member checking, it may be helpful to ask yourself:

- Have I sought feedback from my participants about how I presented their data?
- Did I adjust or revise any portions of my findings that participants did not agree with?
- If there are revisions that I have chosen not to make, have I acknowledged these tensions within my written report?

Memoing

Many qualitative researchers utilize memoing throughout their study design, data collection, and analysis to keep a record of their thoughts, feelings, emotional responses, and questions that arise throughout the inquiry process (Birks et al., 2008). Researchers use memoing as a way to save relevant information about the data that may not be apparent or can be easily forgotten at a later time (Glaser, 1978). Further, by keeping records of decisions and meanings constructed from the data, the researcher can enhance their credibility.

You can keep a notepad of your continued thoughts and questions through each step of the research process. In fact, you can utilize memoing as a side conversation that you have with yourself or among your research team as you analyze your data. While you rarely include your notes within your final research publication, memoing can provide support and enhance your understanding of the research processes, allowing you to understand the data beyond the surface level.

When considering memoing, it may be helpful to ask yourself:

- How does the data make you feel?
- What questions do you still have for your participants or research team?
- Does your data stir any of your emotions or memories of personal experiences?

Positionality

Qualitative researchers often elaborate on positionality within their published work by reflecting upon their identities in relation to their study's participants and data. These scholars often do so because of the epistemological belief that we will never truly, completely, and fully understand truth outside of the context from which it was created. For example, Lincoln (1995) argued that "we can deduce that texts that claim whole and complete truth or that claim to present universal, grant metanarrative, or generalizable knowledge ... are themselves spacious, inauthentic, and misleading" (p. 280). Understanding how a researcher positions themselves within their work is imperative to grasp the meaning and quality of their work. Scholars who support positionality as an indicator of quality argue that appearing detached and claiming objectivity in your work detracts from its quality, and in fact places barriers on how much quality you can truly claim.

In order to utilize positionality within your own work, you must "come clean" (Lincoln, 1995, p. 280) about your own beliefs, identities, and paradigmatic commitments. In order for readers to understand how you have interpreted the data, they must first understand the beliefs that you have about the nature of truth and knowledge. You must also be willing to share your subjective, social, and cultural positions within the larger context of your work.

When considering positionality, it may be helpful to ask yourself:

- What identities do I have in relation to this study?
- How do those identities and beliefs affect the way that I approach and interact with my participants, design, analysis, and which findings I have chosen to report?
- Have I extended my engagement with my own identities beyond simply listing them and critically examined how they affect each aspect of the inquiry process?

Reciprocity

Scholars who embrace the idea of reciprocity argue that we must consider the bonds created between researcher and participant (Lincoln, 1995; McLaughlin and Tierney, 1993). That is to say that each individual participating in the research (which includes us as researchers!) must establish a relationship with each other "marked by a deep sense of trust, caring, and mutuality" (Lincoln, 1995, p. 284). This process can be considered one of purposeful, intense, deep sharing that "opens all lives party to the inquiry to examination" (Lincoln, 1995, pp. 283–284). Those who advocate for reciprocity as an indicator of quality ask how we can share ourselves in relation to the ways that our participants have shared themselves with us.

Indeed, the idea of reciprocity infers that we must be open with ourselves, and our experiences, as researchers both within our interactions with participants as well as throughout our published reports. We often task our participants with sharing their deepest

thoughts, beliefs, and experiences—we are seeking their vulnerability—however, we do not often share ourselves in those spaces as well. As authors of this chapter, we often feel that this ideology aligns closely with Roulston's (2010) conceptualization of romantic interviewing; we share of ourselves to build trust with the participant.

When considering reciprocity, it may be helpful to ask yourself:

- What parts of myself am I comfortable sharing with my participants?
- How can I make the interview space feel more like a conversation in which we both share about ourselves?

Reflexivity

Scholars who engage in reflexivity reflect on their own subjectivities and positionalities, deconstructing how those beliefs and identities shape and are shaped by each aspect of the research process. Reflexivity is the process of turning inward in an effort to recognize and take responsibility for the various ways in which one is situated within the research. Researchers should reflect upon their paradigmatic commitments, their relationship to the study participants, and their beliefs about the research topic.

Some questions to begin reflecting on include: What is your philosophy as a researcher? What is your relationship to the research topic? Answering these questions at the onset of the study allows you to understand how you think about and handle your own influence on the study and to recognize how your own subjectivities and positionalities may impact the creation of research questions. During the data collection process, engaging in reflexivity may include self-reflection in which you seek to understand your emotions and reactions during your interview. By engaging in this self-reflection, you may become attuned to the fact that you have emphasized certain things while shying away from others. During the final write-up, reflexivity may take the form of conscious editing, wherein you fully engage with the data and remain aware of the ways in which your sensitivities can drive what you deem as important. Some useful tools to practice reflexivity include, but are not limited to journaling, self-interviewing, talking with colleagues/peers/friends, researcher memos, video diaries, and poetry/art/music.

When considering reflexivity, it may be helpful to ask yourself the following questions based upon which step of the research process you are currently reflecting:

- Step 1: Finding your research question.
 - Why is this study important to you? Or why did you choose to pursue this study?
 - What do you already know about your topic?
 - What have you experienced?
 - What do you believe about it?
- Step 2: Reviewing the literature.
 - How do previous studies affect the way that you think about your research?
 - How do these other studies relate to your own study?
- Step 3: Figuring out your methods.
 - What do you believe about the nature of truth and reality?
 - What values do you hold related to the inquiry process?
 - How do these beliefs and values align with various research paradigms?
 - How do you feel about your methodological choices?
- Step 4: Collecting data.
 - What personal identities do you have that are related to this study?
 - Which identities do you share with your participants?
 - Which identities do you NOT share with your participants?
 - How do these common and different identities affect the way in which participants will interact with you? Or what kind of data they will choose to share or not share?
- Step 5: Analyzing data.
 - Will your identities lead you to look for specific things?
 - Which findings stand out to you more due to your own experiences?
- Step 6: Writing your findings.
 - How do you choose which of your findings to privilege over others?
 - How will you order your findings?
 - How will you practice transparency concerning your ethical concerns and reflexivity?

Relational ethics

A scholar who utilizes relational ethics “recognizes and values mutual respect, dignity, and connectedness between researcher and researched, and between researchers and the communities in which they live and work” (Adams et al., 2015). Qualitative researchers often form interpersonal bonds with their participants, whether purposefully or organically. When engaging in relational ethics, the researcher takes into consideration those interpersonal bonds and makes decisions in ways that seek to protect them. A researcher focused on relational ethics is often more concerned with creating mutual respect and engaging with their participants than they are

about taking advantage of their participants in an effort to churn out good research. In fact, they often have a sense of reciprocity in which the ultimate goal is to care for, respect, and do justice to and for their participants.

Your consideration of relational ethics may take a variety of forms depending on the type of research that you are engaging in and the ultimate goal of that research. However, all researchers incorporating relational ethics have one shared goal: that decisions be made within the context of the relationships being formed.

When considering relational ethics, it may be helpful to ask yourself:

- Have I considered the relationships I formed with participants while engaging in ethical reasoning?
- Have I ensured that I will not harm the growing mutual respect and care that I have built with my participants?
- Have I invited participants to collaborate during data analysis or within the writing of my findings?

Resonance

Researchers who seek to ensure that their study contains resonance seek to influence readers through evocative representations of the data. The researchers will use their participants' words to create a clear understanding of findings that are relevant and transferable to other areas of study and life (Tracy, 2010). Scholars who are particularly adept at utilizing resonance can often present their findings in such a way as to relate to readers from varied backgrounds.

If you choose to seek resonance within your work, make sure that you write in a way that is clear and concise so that a reader who is not an expert within your field can understand and connect to your study. Rather than leaving a reader to decide how your findings are meaningful, paint a vivid picture using explicit examples pulled from the data to represent your claims.

When considering resonance, it may be helpful to ask yourself:

- Have a *shown* instead of *told* the readers what my findings are by including many direct quotes from participants?
- Have I chosen quotes that are particularly emotional or powerful?
- Have I written my report in such a way that others outside of my field can understand my work?

Rich rigor

A scholar who seeks to claim that they are using rich rigor within their research ensures that they have provided a detailed, clear research design and methodology. From the beginning of the research design, the researcher identifies the purpose of the study and notes every decision made in alignment with the purpose of the study. The author's published methodological process is detailed, and the researcher has collected enough data to convincingly make conclusions (Golafshani, 2003). This is often achieved through data saturation, which refers to the process of collecting data until you no longer encounter new perspectives among your participants.

When considering rich rigor, it may be helpful to ask yourself:

- Did I clearly describe each step that I took in designing my study? In collecting data? In analyzing data?
- Have I presented enough data in my writing to convince readers that the conclusions I have drawn are meaningful and appropriate?
- How can I include other data sources to support my analyses?
- How have my methodological decisions contributed to my ability to create a data set that adequately represents the participants?

Sacredness

Feminist researchers have long argued for the concept of sacredness to be at the center of high-quality research (Lincoln, 1995; Schaefer, 1981). Lincoln (1995) described this concept as concerning researchers with "a profound concern for human dignity, justice, and interpersonal respect ... the collaborative and egalitarian aspects of the relationships created in the research-to-action continuum" (p. 284). Scholars who choose to embrace sacredness often seek to create relationships with participants based on mutual respect between researcher and participant and deep respect for each participant's personal dignity. Lincoln (1995) further argued that sacredness should be used to further explore the connection between the people with whom we are conducting research (fellow researchers, participants, gatekeepers, etc.) and ecological concerns. She additionally argued that if we do not hold sacred our very Earth and how our work affects it, we destroy not only our physical environment but also the human spirit by which we study.

In embracing the concept of sacredness we must choose to design a study that allows us to interact with participants in a way that respects them as unique individuals. For example, we often see this enacted as consistently checking in with participants to ensure that they are comfortable continuing to share their perspectives through multiple interviews, focus groups, observations, or phases within a study, comfortable with how we are portraying them in our final published reports (this can be achieved through member checking), and allowing them to dictate how data collection interactions occur. For example, you may choose unstructured or semi-structured interviews in order to allow your participants to take you on a journey of their choosing instead of sticking to a strict list of questions.

When considering sacredness, it may be helpful to ask yourself:

- What can I do within the interview/focus group/observation to make participants comfortable?
- Have I checked in with each participant to make sure that they are comfortable scheduling a follow-up interview?
- Did I give participants a choice as to where they would like to meet for an interview?
- Have I allowed participants to help shape our conversation within the interview space?

Sharing privilege

In seeking to share privilege we must grapple with the question of *who owns the data*? Do we, as the authors, own the stories that are shared with us that we then published? Or are data always owned by the participants who have shared it with us? Or, better yet, are data owned by the university that houses us as we publish in seeking tenure? [Lincoln \(1995\)](#) argued that “the somewhat dark side of research hides the fact that most of our research is written for ourselves and our own consumption, and it earns us the dignity, respect, prestige, and economic power in our own worlds that those about whom we write frequently don’t have” (p. 285). Sharing privilege is all about interrogating the ways in which we, as researchers, benefit from the lived experiences and stories shared with us by our participants, and then enacting action in a way that shares that privilege or gives back to those who have loaned us their stories.

There are many practical ways in which sharing privilege has been enacted within research studies. For example, [Lincoln \(1995\)](#) shared stories of an author who shared royalties from her book with her participant, even going as far as to contribute to her participant’s mortgage payment when in need, and [Lather \(2001\)](#), who sought to publish alongside her participants in order to ensure that they are given as much recognition for the work as she was. Sharing privilege can look like sharing financial gain you may experience with participants, sharing authorship, allowing participants to share in the decision-making process about what is and is not published, where it is published, and so on. One of our authors, Leia, shared privilege by asking the participant in a single-person case study where they would prefer that Leia donate money that she was awarded after the publication of the article. Originally, Leia had offered to send the award money to the participant, who instead indicated that they did not wish to receive it.

When considering sharing privilege, it may be helpful to ask yourself:

- How would I feel about inviting participants to write with me in exchange for including their name on my final publication?
- How can I share my data, findings, or compensation with organizations or non-profits that tackle issues related to my research?

Significant contributions

Though we do not determine statistical significance in qualitative analysis, we can determine the significant contribution qualitative research has on expanding the literature on a given topic. To be considered a significant contribution, the research question must first address a gap in the literature, whether that be theoretical, regarding professional practices, or overall cultural or moral views ([Tracy, 2010](#)). Our contributions as qualitative researchers can be significant when we address gaps within our existing knowledge and utilize our data to narrow those gaps. Though it is impossible to conduct a perfect study, as long as the research question, methods, and data-driven findings relate to the gap in our existing knowledge, a scholar can argue that they have made a significant contribution to the literature.

When considering significant contributions, it may be helpful to ask yourself:

- Have I thoroughly explored the literature about my topic in order to discover any existing gaps?
- Have I designed my study in such a way as to close or narrow those gaps?
- Are my chosen methods the best choices for exploring these concepts?
- Have I explicitly connected my findings and how they fit within the larger context of existing literature?

Sincerity

Similar to authenticity, a researcher’s sincerity is considered a good measure of quality when they are transparent in the decision-making process of their study ([Seale, 1999](#)). Sincere researchers seek to paint a picture for their readers, explaining the rationale behind the methods selected, how they were conducted in a way that promotes replicability, and the challenges that arose from selecting these methods. When researchers are sincere in their work, they maintain a great deal of reflexivity and recognize personal bias toward their own study and how that may have impacted the decision-making ([Emerson et al., 1995](#)). See our section on *Reflexivity* to identify personal biases and assumptions you bring into your research.

When considering sincerity, it may be helpful to ask yourself:

- Have I thoroughly described and justified why my methods are the best way to answer my research question(s)?
- Did I provide enough information to allow readers to understand what I accomplished using simple terminology that is descriptive enough for another researcher to replicate the steps that I took?
- Have I situated my work among key scholars within my field?

- Have I detailed all of the unexpected challenges or limitations that I encountered during my study?
- Did I include a reflexivity statement in my final report and connect it to any literature that I used to support my methodological decisions?

Sites as arbiters of quality

Scholars who embrace this concept argue that “research takes place in, and is addressed to, a community; it is also accurately labeled because of the desire of those who discuss such research to have it serve the purposes of the community in which it was carried out, rather than simply serving the community of knowledge producers and policymakers” (Lincoln, 1995, p. 280). In other words, knowledge is relational and situated within the communities in which it is created. To seek to objectively understand the world is to work within anti-communal, individualistic, and self-serving ways. By seeking to, instead, pursue a situated and complex knowledge that incorporates other ways of knowing beyond your own is to embrace “a complex intellectual dimension, exercised for the sake of assisting the marginalized on a journey toward greater participation in common life” (Savage, 1988, p. 13). Scholars who utilize sites as arbiters of quality should also be sure to explain how they have supported the communities with whom they conduct research; you should share how you are serving them, instead of allowing readers to assume that your work has occurred in a vacuum in which you, as the researcher, entered a space and left with only the knowledge that others assisted you in producing. Lincoln (1995) argued that “research is first and foremost a community project, not a project of the academic disciplines alone (or even primarily)” (p. 282).

When considering sites as arbiters of quality, it may be helpful to ask yourself:

- Have I devoted sufficient space in my written report to thoroughly describe the community or population that I am serving?
- How can I give back to the populations or communities that have shared their experiences and perspectives with me?
- Have I shared how I gave back to the communities within my written report?

Transgressive validities

Lather (1993) described her goals in creating transgressive validity as a “reconceptualized validity that is grounded in theorizing our practice ... fragmenting and colliding both hegemonic and oppositional codes, [her] goal is to reinscribe validity in a way that uses the anti foundational problematic to loosen the master code of positivism that continues to so shape even postpositivism” (p. 674). This concept was meant to disrupt the foundational, traditional, post/positivist concepts of reliability and validity while also adding newer conceptualizations of validity that correspond to other paradigmatic views such as poststructuralism. She argued that validity must be “a space of constructed visibility of the practices of methodology and a space of the incitement to see, an apparatus for observing the staging of the poses of methodology, a site that ‘gives to be seen’ the unthought in our thought” (Lather, 1993, p. 676). She divided this concept into four framings, which she also refers to as “scandalous categories” (Lather, 1993, p. 683), that we describe below. Transgressive validities are enacted in different ways, depending on which form you pursue.

Ironic validity

Lather’s (1993) conceptualization of ironic validity, which she also refers to as “validity as simulacra” (p. 677) espouses “a strategy of ironic validity proliferates forms, recognizing that they are rhetorical and without foundation, post-epistemic, lacking in epistemological support” (p. 677). A simpler way to engage in this concept is to consider that we can never truly know the original, absolute, objective truth (if one does, in fact, exist), and the research that we create thereby acts as simulations, simulacra, recreations, or reprints of a real, objective reality. We are providing recreated representations of what we learned while collecting data, but what we are producing is simulations of the truth within our own research.

We have recreated Lather’s ironic validity questions (see Lather, 1993, p. 685) to consider when reviewing your own work or the work of others for ironic validity:

- Have I foregrounded the insufficiencies of language in the production of meaning-making?
- Have I presented the concept of absolute truth, itself, as a problem?
- Have I acknowledged how my representations of the phenomena I am studying may be problematic or not endemic to the larger population or current time?
- Have I shared tensions that I may have found within the data as another dimension of the data?

Rhizomatic validity

Lather (1993) described rhizomatic validity, which she also referred to as Derridean rigor, as often used by researchers in order to undermine, unsettle, and center the marginalized others within a system; in doing so, the researcher generates new locally-determined norms to destabilize oppressive order (Lather, 1993). Scholars who seek to utilize rhizomatic validity concern themselves with understanding related contexts and networks of ideas and people-centered around their topic and/or participant(s). In examining rhizomatic connections and networks within your data, deeply interrogate how systemic and structural forces are at play within the world of your participants.

When considering rhizomatic validity, it may be helpful to ask yourself:

- What policies are affecting participants' lives?
- What other people are involved in their experiences?
- How might you be able to explore and present those connections and contexts?

Paralogical validity

According to [Lather \(1993\)](#), the goal of paralogical validity "is to foster differences and let contradictions remain in tension, as opposed to the recuperation of the other into the same that is always imposed at the end of a traditional philosophy" (p. 679). With the intention to embrace complexity, the researcher "fosters heterogeneity, refusing closure" (p. 679) during the data collection and analysis process as they continue to "search for instabilities" (p. 680). Lather also uses the terms Lyotardian paralogy and neo-pragmatic validity to describe paralogical validity. Often, researchers utilizing paralogical validity will prioritize sharing the differences inherent in their data versus seeking to obtain saturation.

When considering paralogical validity, it may be helpful to ask yourself:

- Have I looked for conflicting perspectives within the data?
- Have I explored any tensions inherent within the data?

Voluptuous validity

Voluptuous validity, or situated validity, is the fourth of [Lather's \(1993\)](#) transgressive validities. Lather uses this term to describe an abundance of data—by collecting as much data as possible, we are able to view our data from everywhere, which is directly in contrast with objectivism's "view from nowhere" (p. 682). She argued that acknowledging that we will never know *everything* and that our data is therefore perpetually incomplete and tentative, allows for the space for "others to enter, the joining of partial voices" (p. 682). Researchers, therefore, engage in voluptuous validity by assuming that they are incapable of knowing everything about a situation, and must continuously engage in both their topic and reflexive practice. In order to practice voluptuous validity, we must continually reflect upon ourselves, our decisions, and our perspectives about our data with the understanding that we will never completely understand our topic and/or participant(s). We may seek to continuously gain more information about our data.

When considering voluptuous validity, it may be helpful to ask yourself:

- Have I exhausted avenues of obtaining data regarding my topic?
- Have I ensured that my findings are written in such a way as to not portray an absolute or complete understanding of my topic?

Triangulation

Triangulation is the practice of using multiple data sources to obtain various answers and points of view to your research question. Typically selected prior to recruitment, the researchers intentionally identify and select specific individuals they aim to be represented in the study or multiple data sources that can be used in tandem to create a situated truth among them. Participants or data sources may be of similar or opposite views to provide a variety of context and depth to answer the research questions from multiple lenses. The order in which participants contribute to the study may be determined based on relational power between the participants, by order of participant influence, or completely at random. It's critical to provide opportunities for representation from multiple sources and individuals. [Denzin \(1978\)](#) suggests that when used appropriately, triangulation is a method to increase the overall credibility of your work.

When considering triangulation, it may be helpful to ask yourself:

- How can I counter-balance the voice of one participant with the voice of another? Or the findings from one source with another?
- Have I spent time with each data source? Each participant? Each document?
- Have I been intentional with my recruitment methods in order to ensure representative inclusion among the sources selected to represent the population or phenomenon that I am studying?
- Have I provided a rationale for spending more time on one data source as compared to another?

Voice

Voice refers to the process of weaving multiple voices throughout your research. [Lincoln \(1995\)](#) argued that we must consider "to who speaks, for whom, to whom, for what purpose ... who speaks for those who do not have access to the corridors of knowledge or the venues of the academic disciplines?" (p. 282). Further, [LeCompte \(1993\)](#) argued that qualitative researchers must "seek out the silenced because their perspectives are often counter-hegemonic" (p. 10). We must seek to involve ourselves deeply with our study participants in order to both accurately reflect their voices and understand the contexts from which they speak in order to ensure that our work does not silence or further marginalize them. We also see voice enacted through polyvocality, which refers to the process of including multiple voices and interpretations of your work. Allowing alternate voices to speak through your work, and therefore presenting nuanced representations of thought—and perhaps thereby embracing the tension created by lack of consensus—shows the strength of your work, while also resisting silence, disengagement, and marginalization ([Lincoln, 1995](#)).

It is one of the authors, Leia's, biggest pet peeves when others say that they want their work to "give voice to others." This determinant of quality, along with our team, argues that others already have a voice—we simply must choose to elevate those voices

through our research. One of the easiest ways to enact voice within your work is to simply include more words from your participants than from yourself within your findings section. Choosing to allow your participants to speak to your readers through gratuitous use of quotes enables your readers to understand your participants' experiences through their own words, while your interpretations serve as the glue that connects the quotes together. While it is true that we, as researchers, are responsible for interpreting the data, utilizing *voice* by including quotes from participants allows us to demonstrate that our findings are meaningful. When pursuing polyvocality, we typically track how often we have quoted each participant within our studies, ensuring that each individual's thoughts are represented throughout the report.

When considering voice, it may be helpful to ask yourself:

- Have I included many quotes in order to demonstrate my findings?
- Have I ensured that one participant is not quoted substantially more than others?
- How can I weave the voices of all participants in such a way as to elevate all of their voices?

Worthy topic

Researchers who seek to claim that their topic is *worthy* must consider the significance of the study as it relates to today's literature, society, and personal events. They strive to extend what has been previously known within the literature to newer findings, demonstrating that the traditional findings are still relevant in today's world. Rather than repeating studies or continuously testing theories in the same way, a worthy topic is one that leaves readers intrigued by the work that has been produced (Guba and Lincoln, 1989). Researchers must consider new perspectives and applications of established knowledge in order to add to the field. We may get hung up on the easy topics, resources, and methodologies that are popular, but it is the researcher who strives for a worthy topic to guide their research study that continues to push the boundaries in their field.

When considering if your topic is worthy, it may be helpful to ask yourself:

- Have I considered how this research may significantly contribute to a meaningful, relevant, topic in today's world?
- If I am studying an already well-researched topic, how does my work maintain the interest of readers? How does it add to the ongoing conversation?

Conclusion

Scholars have long debated how to determine quality within qualitative research without consensus. Trainor and Graue (2013) argued that these difficulties result from (1) disagreement as to what makes *good* qualitative research, (2) methodological training and practice primarily embracing quantitative, postpositivist commitments, and (3) the fact that qualitative researchers often seek to understand culturally-mediated and -defined notions of what constitutes as evidence. In fact, researchers often struggle to agree on even the most basic of vocabulary; for example, while some scholars have argued that the notion of *validity*, which stems from traditional quantitative practices, is incompatible with qualitative research (Cho and Trent, 2020; Kvale, 1995; Ravitch and Carl, 2019; Trainor and Graue, 2013; Wolcott, 1990), others have argued for embracing the term in order to redefine it (Lather, 1993). Therefore, it is each scholar's responsibility to choose and justify the quality determinants that fit their theoretical, ontological, epistemological, and methodological commitments. While this level of freedom may seem overwhelming, we argue that it is this very reprieve from traditional postpositivist practices that gives qualitative research powerful impact.

A trip to the salad bar

In section two, we discussed one of our authors, Leia's, metaphor of designing a qualitative project as constructing the perfect salad at the salad bar. Each researcher engages in this process differently, and therefore, even scholars who choose to use the same quality determinants (ingredients) will likely construct their study (salad) differently. For example, Cain and Velasco (2021) described their data quality efforts as follows;

We utilized triangulation (Tracy, 2010), member checking (Tracy, 2010), and reflexivity (Tracy, 2010). Instead of pursuing triangulation in a positivist sense to validate the collected data (Creswell, 2012), we pursued triangulation as a method to "understand the multiple perspectives available" (Glesne, 2011, p. 47). Each of us as the researchers shared our perspectives about Gray's story, and we worked together to negotiate our meanings and understandings in order to build a more credible meaning from the stories provided. Further, we pursued member-checking (Lather, 1986) by sharing our findings with Gray in order to ensure that we were presenting their story correctly, and that we had correctly understood the meanings and connections that they had wanted to portray. Finally, we the researchers shared a reflexivity journal document in Google Drive where we could write about our own thoughts and processes throughout data collection and analysis (pp. 363–364).

In this article, Cain and Velasco (2021) combined triangulation (determinant 3.21), member checking (determinant 3.7), and reflexivity (determinant 3.11). This fit the study perfectly, as it was carried out under an interpretivist paradigm and allowed Cain

and Velasco to consistently check on interpretations made from the data both with each other and with the participant. Other researchers may have utilized these determinants in alternative ways, or combined them with other determinants.

Implications for researchers in education

In this chapter, we sought to explore the complexity of quality in qualitative research and listed 23 widely-used quality determinants. Un/fortunately, we do not anticipate a consensus being accomplished in the field; qualitative methodologists often resist uniformity, choosing instead to embrace the gray areas inherent in the inquiry process—though this lack of clarity can at times feel overwhelming for learners. Previously, scholars have tried to create a unified framework of quality within qualitative research (e.g., Tracy, 2010), but have encountered resistance to their efforts (e.g., Albusaidi, 2019; Gordon and Patterson, 2013).

When engaging in qualitative research, it is imperative for researchers to critically engage with the entanglements they create among theoretical, ontological, epistemological, and methodological decisions and commitments to ensure that they are presenting an argument in which all of the individual pieces align. We hope that this chapter provides a starting point for further learning and exploration of quality in qualitative research.

Triangulation: origins and definitions

In its basic formulations, the term triangulation designates the use of more than one perspective—in terms of method, theory, observer or data source—in the study of social phenomena, although over time more emphasis has been placed on the use of multiple methods of investigation and data sources (Bryman, 2016; Maxwell, 2016). Its use is aimed at producing more accurate, thorough and objective representations of the research subject; in other words, it is aimed at reinforcing the validity and/or the credibility of our research findings. Originally used as a heuristic tool in the context of military and geographical sciences to indicate the method for locating the position of points in a field through the combined use of three perspectives (Smith, 1975; Cox and Hassard, 2005; Konecki, 2008; Abdalla et al., 2018), triangulation eventually came to be widely employed in the social sciences through the work of several scholars in different fields (Campbell and Fiske, 1959; Webb et al., 1966; Smith, 1975; Denzin, 1970, 1978, 2006, 2001, 2012). Indeed, not all uses of multiple theories, methods, observers or data sources are commonly seen as triangulation. Similarly to other scholars (such as Hammersley and Atkinson, 2007; Heale and Forbes, 2013), Schwandt (2015, p. 307) describes the “central point” of triangulation as “to examine a conclusion (assertion, claim, etc.) from more than one vantage point”. This stance is consistent both with the original definition of triangulation in surveying and navigation (the use of multiple observations to determine the location of a particular object) and Denzin’s subsequent definitions (Denzin, 1970, 1978).

Without explicitly using the term triangulation, Campbell and Fiske (1959) introduced the concept to psychology, so as to empirically test the results obtained using different quantitative techniques (Abdalla et al., 2018). They used it as a synonym for convergent validity, that is, the degree to which different measurements related to the same or similar theoretical constructs are correlated. A few years later, Campbell and colleagues (Webb et al., 1966) coined the term *triangulation*, referring to the use of multiple methods to analyze and interpret the same data set and obtain valid results, in other words, providing a close representation of the phenomenon under investigation. Smith (1975) used the term triangulation as a metaphor to describe a research strategy borrowed from navigational or military practices: in the same way as navigators use maps and multiple reference points to locate an object’s exact position, social researchers can improve the accuracy of their findings by collecting different types of data on the same phenomenon. Finally, in 1978, Norman Denzin defined the process of triangulation as “the combination of methodologies in the study of the same phenomenon” (1978, p. 291). He described four types of triangulation: across different data sources, across different theoretical perspectives, across and among different researchers, and across data collection methods.

If disagreements on the initial use of triangulation within the social sciences seem to persist¹—for instance, according to Oppermann (2000), Webb et al. (1966) were among the first to introduce the term triangulation as a research approach in the social sciences, while Heesen et al. (2019) maintain that the first to advocate and apply “methodological triangulation” was the American sociologist Du Bois (1996/1899)—Denzin is unquestionably the scholar who has most widely employed, promoted and discussed triangulation in its comprehensive form and definition. In its early formulations, Denzin (1970, 1978) described triangulation as a combination of data, theories, investigators and methods to study the same phenomenon, whose aim is to overcome partial views and provide something very close to a comprehensive and reliable picture of the phenomenon.

Data triangulation refers to the collection of different sets of data in different periods of time and from different sources and places in order to obtain richer, deeper and more detailed accounts of the social phenomena under investigation. For example, a researcher interested in studying the changing nature of relationships, intimacies and families might collect several types of data (qualitative, quantitative or both) in different countries, from different subjects, at different points in time. *Theoretical triangulation* means using multiple theories or theoretical frameworks, sometimes from diverse disciplines or areas of knowledge, to interpret and analyze the same social phenomenon or set of data. For example, a researcher interested in studying the phenomenon of refugees and asylum seekers in Europe might use different theoretical frameworks drawing on theories on migration, citizenship, feminist theories, theories

¹See also Bryman (2007), Cho and Trent (2006), Creswell and Clark (2010), Ellingson (2009), Fielding (2012), Guba and Lincoln (2005), Moran-Ellis et al. (2006), Teddlie and Tashakkori (2011) and Yin (2015). According to Maxwell (2016), the use of the term triangulation was implicitly present even earlier, especially in the natural sciences.

on globalization, emotions, capitalism, and so on and so forth, from similar or different disciplinary perspectives (such as sociology, political sciences, economic sociology, anthropology, social geography, history, social psychology, etc.). *Investigator triangulation* involves the utilization of different researchers (an evaluation team) in the study of the same social phenomenon and the analysis of the same set of data. For example, a researcher who wants to study the long-term psycho-social effects of a global pandemic in a country might make use of a team of different researchers (possibly from different disciplinary fields) in order to achieve an in-depth, thorough interpretation of the data based on varied perspectives, considerations and analyses. *Methodological triangulation*, which is the most widely employed type of triangulation, refers to the use of multiple methods to study the same social phenomenon. For example, a researcher interested in studying the multiple implications and meanings of informal care with a phenomenological approach might make use of in-depth interviews, participant observation, questionnaires, diaries, video-recorded material, pre-existing databases, archives, etc. in order to obtain a more complete data set and a better understanding of the phenomenon.

According to Denzin's original definition (1978), the combination of different methods to study the same phenomenon and the convergence or agreement between the different methods increase the possibility that the research findings are not the result of a methodological artifact and reduce the shortcomings and limitations of a single method, thereby producing more credible conclusions. In other words, triangulation means analyzing the same phenomenon or research topic through more than one lens and from different angles and perspectives in order to shed new light on that phenomenon, reduce subjective and methodological biases, and increase the possibility of reaching more credible (or "valid") and replicable findings (Abdalla et al., 2018; Denzin and Lincoln, 2011; Flick, 2007; Maxwell, 2012; Patton, 2014). The usefulness of the four types of triangulation (data, theoretical, investigator and methodological triangulation) as a strategy for more thoroughness, comprehensiveness, accuracy and depth in any research is also reiterated in more recent publications (Denzin, 2006; Denzin and Lincoln, 2011). However, since its early formulations, different stances have been embraced and developed by different scholars with regard to the nature of triangulation (qualitative, quantitative methods or both?), its main goals (in terms of the validity, reliability or consistency of the results) and its relationship with different research paradigms (constructivism, positivism, postpositivism, and so on). So, let's now have a look at some of these more recent developments and debates in the literature on these subject matters.

Further developments in the literature on triangulation

Denzin himself highlights how "in its original forms (Denzin, 1970), triangulation referred only to the use of multiple forms of qualitative research methods, not the combination of quantitative and qualitative methods. It was also understood that each qualitative methodology—life story, case study, interviewing, ethnography, participant observation—rested on specific epistemological assumptions and each method had a complex disciplinary history. Hence, these interpretive methods could not be easily combined with one another" (Denzin, 2012, p. 82). In this article, not by chance entitled "Triangulation 2.0", Denzin (2012) revisits the multiple challenges of triangulation and proposes a sort of third way of conceptualizing mixed methods research based on critical interpretive methodologies. After illustrating some of the key controversies raised about mixed methods research—including disagreements over definitions, the real nature of a mixed methods study, debates on alleged irreconcilable differences between paradigms, contemporary preferences for postpositivism (Ellingson, 2009), and the added value of mixed methods—Denzin concludes by repeating what he thinks the "researcher-as-bricoleur-theorist" working between and within competing and overlapping perspectives and paradigms should do: act as a catalyst for positive social change through emancipatory action, and inspire readers and audiences toward this goal.

Can we retake the discourse surrounding this word [triangulation] and retrofit it to a postmodern world where meanings and politics are refracted off of the edges of crystals, not triangles? Can we train methodological bricoleurs who seek new third ways through and around obstacles to social justice in a neoliberal world? Can we create a discourse that does not play word games with itself, in methods-centric ways (Hesse-Biber, 2010)? Can we chart a way out of the present? Can we have a moratorium on mixed methods talk about designs and typologies and get back to the task at hand, which is changing the world?

Denzin (2012, p. 85).

For Denzin, triangulation is typically a qualitative tool. According to other scholars, on the other hand, triangulation involves the employment of both quantitative and qualitative methods (Konecki, 2008; Hammersley and Arkinson, 2007; Miles and Huberman, 1994; Moran et al., 2006; Silverman, 2001). Thus, the term triangulation assumes slightly or substantially different meanings depending on type and use. Konecki (2008) offers some methodological and epistemological considerations related to how to construct the "quality" of qualitative field research. The author clarifies how triangulation as a methodological tool is not only confined to positivist approaches, but can and should be used in field research in order to enhance the credibility, validity and objectivity of the research conclusions. His accent on a typically positivist lexicon, though, seems to be a bit at odds with his epistemological premises. In qualitative methodology, he claims, "the use of this procedure [triangulation] is often justified by the scientific requirements of gaining 'reliability' (it is an opportunity to repeat the observed behaviors together with the explanations, which means the accuracy of the 'measurement' or classification), validity (the answers to the question whether the explanations are suitable to present quantitative descriptions of people or situations), credibility (the degree of probability of occurrence of the observed phenomena), or the opportunity of generalizability" (Konecki, 2008, p. 23).

Heesen et al. (2019) compare and contrast methodological *pluralism* and methodological *purism* and define triangulation in terms of those methodological strategies used to strengthen the reliability of results obtained in the social sciences. Using examples taken from voting theory, the authors show how the use of multiple methods and convergence upon a single conclusion better supports the findings, increasing their validity and credibility. Their focus, therefore, is mostly on methodological triangulation, ignoring the other types. Reflecting on the origins of the term triangulation, its multiple connotations and its multiple potentialities, Opperman (2000), similarly to Denzin, highlights how the basic concepts underlying triangulation can be easily misunderstood. Often interpreted as an approach that combines both quantitative and qualitative data collection, triangulation—characterized by cross-linkages between and the systematic planning of these collection methods—is confused with multi-methodological approaches, in which there is limited cross-validation of the results.

Another common misconception is that the goal of triangulation is to achieve consistency across data sources or approaches (Guion et al., 2011; Patton, 2014). The belief that this research strategy provides convergence toward a single and coherent conclusion may be one of the most detrimental assumptions. Indeed, quite often the data produce inconsistent or even contradictory findings. Yet, these inconsistencies or contradictions should be seen as an opportunity to unravel the complexity of the phenomenon under inquiry and disclose a more in-depth understanding and interpretation of the data. Such an opportunity is clarified, among others, by Deacon et al. (1998), who illustrate an example of a multi-method investigation on the relationship between social scientists and the media in which the qualitative and quantitative findings appeared to contradict each other. Far from disconcerting or discouraging the authors, the clash between the two sets of findings allowed them to reflect upon and provide indications on how to explain and deal with these discrepancies. This case study shows the benefits as well the challenges of mixed-methods research. Accepting the internal validity of different sources of evidence and attempting to draw up alternative explanations induced the researchers to reassess their preliminary findings, while at the same time warning them that the issues may have been more complex than they had initially supposed and encouraging them to develop more convincing and robust explanations of the social processes being investigated.

Inconsistency and/or contradiction between data is actually explicitly posited by Mathison (1988) as one of the main purposes of triangulation. Her claim is that the researcher can analyze inconsistent or contradictory data to construct different, plausible explanations based upon multiple layers of evidence. Each of these layers can enable the researcher to produce richer, more in-depth descriptions and more credible explanations of the phenomenon being studied. Whichever conception of triangulation is employed in qualitative research, the end result is an increase in the *credibility* of the findings. The undisputable fact that triangulation adds depth to the data collected and analyzed is also reiterated by a recent publication (Fusch et al., 2018) which is specifically devoted to reconsidering triangulation in qualitative research. Criticizing scholars who, during the last decades, allegedly attempted to provide alternative approaches to triangulation but, in reality, merely proposed a restyled version of Denzin's approach, the authors discuss the continuing relevance of Denzin's approach to the triangulation of data, providing novice researchers and doctoral students with a series of useful recommendations on how to maximize its benefits. One of the best pieces of advice is that "researchers should identify the seminal (original) sources in their reading and critically read the seminal scholars' work to ensure that they are not creating more ambiguity. [...] Novice researchers should keep in mind that the triangulation of data can result in sometimes contradictory and inconsistent results; however, it is up to the researcher to make sense of them for the reader and to demonstrate the richness of the information gleaned from the data" (Fusch et al., 2018, p. 26).

To conclude this review of some of the main issues at stake when discussing the "used, abused and misinterpreted" term triangulation (Denzin, 2012, p. 85), it may be worth recalling a final, recent paper providing a systematic analysis of triangulation typologies and, through it, discuss the following dimensions in qualitative research: reliability, credibility, transferability and confirmability (Abdalla et al., 2018). Once again, this paper sets out to provide some guidance to researchers and this is why I mention it here. In particular, the authors illustrate some strategies on how to improve credibility in qualitative research and point to some advances in the discussions about the use of triangulation and its accomplishments in terms of research quality, essentially vis-à-vis rigor, scale, complexity, variety and depth in sociological research. It would be outside the scope of this chapter to comprehensively cover current and past debates on the uses and abuses of triangulation in the social sciences. Hence, in what follows, it may be useful to provide a couple of examples of triangulation, while making reference to Denzin's typology: the first example combines *theoretical, data and methodological triangulation*, and the second one includes an interesting and atypical example of *investigator triangulation*. Let us have a look at them both.

Triangulating theories, data, methods and analytical strategies: an American study on the phenomenology of care

The first example is based on a research project on family care, which I conducted a few years ago in Philadelphia (Pratesi, 2012, 2018). The overall aim of the research was to develop a 360-degree phenomenology of care by focusing on different kinds of care arrangements as they emerge in different types of family contexts and other forms of intimate relationships. Another aim of the research was to overcome the limitations of a traditional study on the gendered division of care work by focusing on a less investigated aspect of care: its *emotional implications* in terms of inclusion/exclusion. This in-depth, phenomenological analysis of the relational, interactive and emotional dimensions of informal care aimed to shed light upon the dynamics through which inequality is reproduced situationally, beyond the rigid and reifying categorizations of sex, sexuality and gender.

One of the research goals was to reflect upon the possibility of an embodied social theory of care; a theory aimed at reconciling the micro- and macro-aspects of social life by looking at the lived experience of care as an emotionally charged experience with important sociological and political implications. The analytic perspective I presented in this work provided a more detailed description of the person *who cares* and a broader phenomenological approach to the issues of care and care-related inequalities.

By looking at people's narratives about their *lived* and *felt* experience of care, this study offered a better understanding of the phenomenon of care, its multiple and not-so-visible purposes and implications, and, ultimately, its core nature.

Hence, the first type of triangulation I had to deal with was a *theoretical triangulation*: in practical terms, I had to handle at least three oceanic kinds of literature—on care, gender and emotions. Moreover, each of these fields of studies was further divided into several other areas and theoretical strands—the literature on care included the differences between formal and informal care, feminist theories on care, the ethics of care, etc.; gender included sexualities, feminist theories on gender and sexualities, theories on intersectionality, etc.; and the sociological theories on emotions are manifold. Therefore, it was not only necessary to use theoretical triangulation to come to terms with such complexity, but also to find a path to follow to prevent me losing my way. So, let's now have a look at what types of theories and theoretical frameworks allowed me to circumscribe and navigate the lived experience of care.

The theoretical background of this research considered the heuristic and epistemological potential of *phenomenology* for a critical understanding of *symbolic interactionism* and *ethnomethodology*. These traditions of inquiry seemed the most suited to obtaining an insight into the multiple ways through which emotional dynamics shape the caregivers' experience of care and produce different outcomes in terms of equality/inequality, inclusion/exclusion, belonging and entitlement to rights; in other words, in terms of citizenship. The *phenomenological perspective* allowed me to highlight the natural but not necessarily evident links between *symbolic interactionism*, *social constructionism* and *ethnomethodology*, the latter being more specifically identified with the approach of Sarah Fenstermaker and Candace West (2002). The authors conceptualize gender in terms of a fluid, contingent and situated accomplishment through which outcomes of inequality are constantly reproduced (Fenstermaker and West, 2002). They use the expression *doing gender* to suggest that the performative aspects of gender can be interpreted and understood as a way of *doing difference*. My argument is that a careful, phenomenological investigation of the processes involved in *doing care* can provide significant clues to interpret and visualize the concept of *doing citizenship*, in other words, the multiple ways in which inequalities and dynamics of inclusion/exclusion based on socially constructed categories result from ongoing interactional accomplishments. Care environments are places where dynamics of inclusion and exclusion are constantly produced; therefore, they are a strategic site for revealing the invisible, emotion-based interactional mechanisms through which social exclusion and inequality, on the one hand, but also social inclusion, status membership and citizenship, on the other, are constantly reproduced at the micro-level of analysis.

From the point of view of care theorists, the study drew on those approaches that suggest that examining care within specific historical and social contexts might be the most effective way to grasp a fuller understanding of its place and meaning in people's lives. *Care is a particular kind of work*, an activity directed toward identifying and meeting the needs or the well-being of certain others and challenging dichotomous thinking and dualisms which oppose *head* with *heart* and *rationality* with *emotion*. Hence, a different type of rationality is needed to understand care (Wærness, 1984), one compatible with but more substantive than the formal rationality by which orthodox economists analyze labor supply decisions. Care activities are different from but need to be integrated with other activities in both the economic and political spheres (Hochschild, 1983; Zelizer, 2005; Folbre and Nelson, 2000), and the increasing intertwining of *love* and *labor* calls for innovative research perspectives and theoretical formulations. From the point of view of the theories on emotions, the study drew on those approaches to the sociology of emotions which establish important links between the micro- and macro-levels of analysis by showing the emotional mechanisms through which the social bond, social behavior and social structures are interactionally and situationally reproduced. More specifically, Collins' *Interaction Ritual Chains* model was used (Collins, 2004).

In order to shed light on the links between the private, inner emotional processes related to care and their public, social and structural outcomes, I needed data collection methods that could capture and visualize the emotionally charged and lived experience of care in different types of caregivers; that is, methods that could be innovative, creative and reliable enough to allow me to claim the credibility of my findings and to induce the reader to endorse my view. Thus, from the methodological point of view, the research drew on a multi-method approach which involved: semi-structured in-depth interviews; weekly diaries on the emotional experience of care; participant observation; online discussion forums for members of parents' associations; ongoing conversations with the respondents beyond the interview context; key informant interviews; and secondary sources on informal care and parenthood collected from adoption agencies, local associations and online forums, journal and newspaper articles, and the web. Since I was the only researcher involved in the study, the entire data collection process was extremely time-consuming.

Being aimed at eliciting answers that could enable the emergence of the caregivers' "felt experience" of care and their stories, the interview format was extremely complex and included, among other research tools, a *thermometer of feelings*, an *existential ladder*, vignettes and several images of care (*photo elicitation*).² After the interview, out of all the respondents, a small sample accepted to

²The *thermometer of feelings* involved asking interviewees to qualify and weight a series of emotions related to their care responsibilities and activities. Interviewees were given a board with the drawing of a thermometer and twenty tags, representing twenty different emotional states, and then asked to locate the tags on a scale ranging from zero to one hundred while simultaneously commenting on their choices. Showing the interviewees a drawing of an *existential ladder* (a simple set of steps), I asked them to locate themselves on the ladder vis-à-vis their present, past and future situation, and then to describe what each of the steps represented for them. I then ask questions to understand whether and to what extent their care responsibilities affected their professional and existential careers in the past or present, and if there were alternative pathways they had to renounce. This apparently simple tool allowed me to collect a diachronic, multidimensional and holographic picture of their biographical pathways instead of a mere snapshot of their present situation. Moreover, it allowed me to get in-depth, fine-grained insights not only into the interviewees' existential and professional trajectories, but also into their inner emotional dynamics and motivations. *Photo elicitation* was another fundamental tool of the in-depth interview. At the end of the interview, I showed the participants a series of images of care in different contexts and situations (positive, neutral and negative) and asked them to choose those which best illustrated their *feelings* when thinking about their *lived* and *felt* experiences of care. These visual prompts stimulated rich accounts of the respondents' subjective interpretations and the emotional states they associated them with, and allowed me to access a deeper level of meaning and understanding. Through photo elicitation, the meanings of care became much more complex, at times even contradictory, but the result was a multi-layered, deeper ethnographic understanding of the phenomenon of care. For a more exhaustive description of these research tools, see Pratesi (2012, 2018).

keep a record of their daily care activities for three to four subsequent weeks. The *time sampling diary* (Brandstätter, 2001) is a research technique designed to gain insights into people's subjective experiences as they go about their daily activities, with a specific focus on the emotional dimension attached to such activities. The diary covered a 24 h period over two days (of choice) in three subsequent weeks and focused on the emotional states experienced by the respondents in different care contexts and moments. It focused on the type of care activity, time, place, other activities involved, their perception of resources/constraints and the eventual presence/absence of other persons. Even though the response rate for the diaries (22) was not sufficient for them to be attributed the same importance as the in-depth interviews in the analytical process, the richness and the quality of the data collected through this tool were invaluable.

The other form of triangulation I used in this study was *data triangulation*, to be intended here in terms of the collection of different sets of data, in different periods of time, and from different sources and places. Overall, the study involved meeting, interviewing and observing 80 informal caregivers, of whom 38 self-defined as heterosexual and 42 self-defined as gay and lesbian. The empirical part of the study lasted approximately two years, developing mostly between the winter of 2005 and the end of summer 2007, and involved several sources of data collected over time in different contexts. With the exception of a single father living in New York City, all the respondents lived in the urban and suburban areas of Philadelphia. The purposive sample included a variety of caregivers: partnered/married and single caregivers, male and female caregivers, heterosexual and gay/lesbian caregivers. On the other hand, the sample was relatively homogenous in terms of social class and type of care. The principal type of care involved in my study was childcare, but the sample included some cases of elderly care as the goal was to get a broad, exhaustive picture of the care phenomenon.

To construct the sample of married, cohabiting and single caregivers, I started from two local children's centers (a day care and a parent-infant center), informal networks, colleagues and two local LGBT associations. Getting in touch with gay/lesbian caregivers was more than difficult than anticipated; I therefore started to use several data collection channels involving: placing flyers in local schools, LGBT centers and activist organizations, gay-friendly cooperatives and a local gay bookstore; sending announcements via email through the mailing list of a local association of gay and lesbian parents and other local organizations; attending parents' events; creating new networks also through a yoga center. The purposive sample was eventually enlarged through snowball sampling for all the different kinds of caregivers. Secondary material and gray literature on public and private childcare centers, local organizations dealing with informal care (childcare and elderly care), local schools and associations, representatives of LGBT associations, LGBT parents associations, etc. were also collected together with many other sources of information which helped me to piece together a wide-ranging interpretive puzzle of the phenomenon of care with its multiple implications.

In terms of the analytical process that I used to interpret my data, I might perhaps mention a final form of triangulation which I shall call *analytical triangulation*. Indeed, the analysis of the substantial amount of qualitative data collected during the two years was guided by what Denzin calls *interpretive interactionism* (Denzin, 2001a) and what other scholars call *interpretive phenomenological analysis* (Smith, 2004). This analytical approach involves trying to understand the individuals' life experiences, what meanings individuals attribute to their experiences and how they make sense of them (Smith, 2004). These meanings were captured through the analysis of the interactions between the caregiver, the person cared for and a whole set of generalized others. Consequently, the analytical approach I adopted can be defined as *phenomenological*, *interactionist* and *interpretative*, in that it is concerned with the individuals' perceptions or accounts of a social phenomenon, focuses on people's subjective experiences and interpretations of the world, and views the analytical outcome as resulting from the interactions between the individuals' accounts and the researcher's frameworks of meaning.

The combined use of a *constant comparison* and *analytic induction* enabled the ongoing and systematic emergence of hypotheses directly from the data. Thus, although the research had a solid background based on a complex theoretical triangulation, as I mentioned, an emotion-based, micro-situated and relational theory of care was developed and deeply grounded in the qualitative data. As the data collection and analysis advanced, central theoretical concepts and emerging themes were identified and links were developed between those concepts and the collection of new qualitative data. The early stages of empirical research, especially when it also involves ethnographic work and observation, tend to be quite open, laborious and time-consuming, but also extremely productive. The subsequent stages of the research involve the constant corroboration, comparison and systematization of the emerging ideas, concepts, hypotheses and patterns. The whole process never really ends and could continue indefinitely: essentially, it ends when the researcher decides to or has to end it because of time and resource constraints.

Among other things, the research findings showed how same-sex families distanced themselves from hetero-normative definitions of family while simultaneously avoiding marginalizing definitions of "*parental citizenship*" based on hegemonic and heterosexist conceptions of sexuality and parenthood. Emotions make up the (missing) link between *doing care* at the micro-level of interactions and *doing or undoing difference* at the macro-level of social structures, beyond the rigid and reifying categorizations of sex, sexuality and gender; and different ways to *do care* and to *do gender* must be taken into account if we want to grasp a truly comprehensive and panoramic picture of the phenomenon of care and its *whatness*. It was one of the aims of the study (Pratesi, 2018) to highlight "the centrality of emotions to routine operations of social interaction" (Barbalet, 2001, p. 3) and their explanatory role in producing social change. Indeed, it revealed and clarified the emotional dynamics through which forms of relational social inclusion are produced at the micro-level of interactions even when forms of inequality and social exclusion persist at the

macro-level of social structures. More specifically, it clarified the interactional, emotional dynamics connecting parenthood, sexual orientation and citizenship and the complex ways they are shaped by and shape the structures in which they are embedded, producing social change. Ultimately, it clarified the extent to which empirical research can create contexts of learning and growth where the pleasure of knowledge is never merely cognitive or intellectual. By *doing care* we also *do citizenship, social inclusion and social change*: through emotions.

Triangulating theories, data, methods and investigators: innovative UK research on care-related technologies

Still related to “care”, but from a totally different perspective, the second example of triangulation concerns a pioneering project (2009–2011) which was conducted in the context of the UK government’s “ageing-in-place” policy aimed at enabling older people to live independently and safely within their homes and communities thanks to the use of smart, innovative technological solutions (Pratesi et al., 2012, 2013). The research aims and objectives included: identification of older people’s technological, psychological and social needs; definition of user requirements to inform an activity monitoring system for use in private homes and residential care settings; and analysis of the ways in which such systems impact on the everyday lives of older adults in different settings. The project was designed to develop an intelligent activity-monitoring system to support older and/or disabled people’s independence, safety and quality of life by charting activity/inactivity patterns in their living environments. What made this system “smart” and particularly innovative in comparison with other activity monitoring systems was its capability to learn patterns of behavior and over a period of time identify deviations from the norm. These deviations might indicate the presence of a problem and the necessity to intervene. Therefore, the innovative aspects of the system consisted of its capacity to go beyond mere safety and emergency issues (such as fall detection) and monitor both *health-* and *well-being-related* issues, through its ability to read and interpret *behavioral* deviations from the norm (such as not entering the kitchen). Being based on infra-red thermal images—which meant that neither the persons nor their specific activity could be identified—the system ensured complete respect of privacy. Nevertheless, at the same time, the system aimed to provide a much richer type of information than existing home monitoring systems that rely on sensors such as door switches and conventional movement detectors. Thus, for example, the system was also able to detect the presence or absence of other people in the house, the exact location of the person(s) within a specific room and if the person was sitting or lying down. In terms of design, it was intended to be similar to a smoke detector, therefore increasing privacy and avoiding the risk of potential stigmatizations connected to the use of assistive technologies.

The *theoretical triangulation* was based on extensive literature reviews on several disciplines and areas of study which included: aging and ageism; gerontology; gerontechnology; assistive technologies; telecare; user-driven, person-centered participatory research approaches; older adults as co-researchers; innovative research; behavioral symptoms of diseases; independent and safe aging at home, etc. The *methodological* and *data triangulation* were grounded on a number of different research tools, methods and sources of information, which included: secondary analysis of existing datasets from previous studies on aging and technology; face-to-face, in-depth interviews with older people who live alone at home; telephone interviews with professional stakeholders and health-care professionals; focus groups with older people and their formal and informal carers; workshops and quarterly meetings with the members of the advisory group; home trials of four to six months’ duration conducted on the prototype system; face-to-face interviews with the home trial participants and their informal carers; home trial participants’ diaries; vignettes and case studies.

The first phase of data collection yielded a considerable amount of qualitative data and resulted in the development of a series of use case scenarios³ which were designed to focus attention on the needs, motivations and perspectives of older people together with the potentialities and challenges of ambient-assisted living technology. On the basis of these qualitative data, a User Requirements Report fully grounded in the older people’s experience of the activity-monitoring technology was produced and a prototype infrared activity-monitoring system was developed by the team of technologists. Home trials aimed to assess the capacity, potentialities and acceptability of the activity-monitoring system within domestic settings. Data on the person’s activity in the house were collected via a number of infrared sensors and analyzed by the team of technologists. During the period of the home trials, pre- and post-home trial interviews were conducted with the participants and their informal carers and the participants were asked to keep a diary. The purpose of the diary was to provide a place for them to record information about their daily living activities. The information provided was then used to help improve the system and its response to events taking place in the home.

From the point of view of the *investigator triangulation*, we adopted a person-centered participatory approach to ensure that the needs, perspectives and preferences of older adults were taken into account throughout the process. The project was conducted in partnership with (1) a UK academic institution, represented by a research team of sociologists, (2) an industrial partner, represented by a team of engineers, and (3) an advisory group of older people, whose role was to provide systematic input into the research design and development, including data collection, analysis and dissemination. The advisory group was composed of six older adults from different cultural, social and occupational backgrounds. Participatory processes and/or user-driven approaches tend to include users (in this case, older people) simply as “test subjects” in the evaluation of already developed technologies. The innovative aspect of our more inclusive person-centered approach was the involvement of older people throughout the entire research

³Use case consists of a number of hypothetical scenarios, each representing specific situations and settings (domestic settings, institutional settings, etc.) and specific problems (a fall, a stroke, not being able to call for help, unusual, prolonged periods of activity or inactivity within the home, etc.), which were co-constructed with the advisory group of older adults and discussed by the three research teams. Each use case scenario was analyzed with the goal of figuring out both potential outcomes and strategies to deal with them.

process. To provide a sense of agency and equality in the research process, the members of the advisory group were considered co-researchers from the outset. As part of this participatory approach, they were actively involved in determining their level of participation and their role as co-researchers. All members of the advisory group agreed to review documents and relevant articles and provide input in the decision-making process. In addition, some expressed their desire to be involved in the data collection aspects of the research, creating the opportunity for the advisory group members to be directly involved in interviewing other older people and the potential to capture experiences which might not otherwise have emerged.

During the first year of the project, the members of the advisory group who opted for a more active involvement in the research process were provided with the necessary skills for interviewing and co-conducting focus groups via training workshops offered by the academic research team. Together with guidelines on how to conduct semi-structured, in-depth interviews, the training workshop provided advisory group members with the basic skills necessary to interview other older people within the community and to attend focus groups as co-researchers. Although the co-researchers felt that the training was stimulating and empowering, only three members of the advisory group felt that they had the necessary skills and confidence to be actively involved in the data collection and analysis. The benefits (and/or the shortcomings) of the participatory process were evidenced in the constant communication and interaction between the academic team and the advisory group of co-researchers throughout the project. From the outset, the members of the advisory group were provided with a broad range of possible forms of communication. This included: quarterly meetings with the research partners; face-to-face, Email and telephone contacts; the circulation and distribution of project-related reports, minutes and documents and information related to assistive technology, academic papers and journal articles, conference proceedings, seminars and outputs from other relevant events. As the research went on, these forms of communication were developed and became the primary means for transferring and sharing information between the academic team and the advisory group of older people. The members of the advisory group were encouraged to express and share their thoughts, feelings and opinions on events, meetings, research progress, status reports, latest news on assistive technologies, relevant websites, forthcoming conferences and articles, and to provide the academic team with regular feedback.

This approach facilitated the development of a continuous two-way dialog between the research team and the advisory group of older people, in a constant flow of information that was capitalized upon by the research team to reshape the scope of the research and refine its tools and methods. This process was enlightening for the research team, revealing issues that would not otherwise have been revealed, as the advisory group members were drawing on their own lived experiences. Their involvement provided crucial and critical insight into the potential impact of home monitoring technology on people's habits, behaviors and feelings; people's sense of privacy, autonomy, safety and independence; and finally, issues concerning personal identity, sense of belonging, the aging process and the symbolic meanings of home. In light of this continuous input, elements of both the sociological research process and technological development were reshaped or amended and the advisory group members reported that they felt empowered, more knowledgeable about activity-monitoring technology and able to have their voices heard and valued through this platform.

A key component of participatory research is including, acknowledging and making productive use of every participant's input (McCreadie and Tinker, 2005; Reed et al., 2004; Ross et al., 2005; Van den Hove, 2006; Warburton et al., 2009). As the project progressed, the comments and suggestions of the advisory group were incorporated into the research, with the expectation that the final outcome would be reflective of their experiences, values and needs. At this point, it is necessary to recognize and clearly state the trade-off between the system's technical capabilities (i.e., what *cannot* be designed) and requirement to incorporate user requirements into the system (i.e., what *can* be designed). This is as much about the users understanding the technical capabilities and limitations as the need to ensure that user requirements get put into the system design. The failure to consider this may well result in tokenistic and disingenuous participation and a system that is divorced from the everyday lives of older people.

The user-driven participatory approach we adopted also presented some challenges, and its management was not always successful. Participatory research is a continuous interactive process that must be constantly renewed and renegotiated. Undertaking participatory research requires the academic team to consider the requirements of all partners, co-researchers and stakeholders while at the same time maintaining high standards of research. This often requires working with each partner individually to reassert the benefits of taking this type of approach. Indeed, some of the main challenges we encountered in this project were maintaining high levels of collaboration, motivation and enthusiasm among the co-researchers while simultaneously facilitating the dialog between the different requirements of the advisory group of older people (co-researchers) and the team of technologists. At the beginning of the project, it was clear that the team of technologists were not necessarily very enthusiastic about involving the advisory group of older people in each and every stage of the project. On the other hand, the members of the advisory group were eager to be involved in the different levels of participation, that is, attending meetings, reviewing documentation, engaging in data collection and analysis, etc. As a result, flexibility became the byword in terms of role expectations while allowing the individuals themselves to determine and shape their level of involvement in the research. There was a fine line between ensuring that the older people made a positive contribution while sustaining their effort over the course of the research. A further important issue regarded the different work ethos, cultures and practices of the research partners involved. Whereas the academic research team had a consolidated tradition of conducting participatory research and a solid and grounded understanding of the ways in which participatory research must be conducted and whom it should benefit, for the technology partners the concept of participatory research was relatively unknown and alien to their traditional ways of thinking and working. Moreover, whereas the industrial partners were evidently and explicitly focused on the goal of producing a successful and marketable product, the academic team and the advisory group were concerned with the social, psychological and emotional effects of this type of care-related technological device and its potential impact on people's everyday lives. In this context, we assumed a bridging

role so as to mediate between the different research partners and ensure an authentic participatory process; nevertheless, the efficacy of this role was not always granted.

Regardless of these shortcomings, this example clearly shows how in certain contexts, *researcher triangulation* is not only valuable but necessary. The involvement of older people in research on ambient-assisted living technologies was key to achieving meaningful and ethically acceptable findings. Care-related technologies can create and expand opportunities for older people's empowerment, safety, independence and well-being. Nevertheless, they also involve important ethical issues concerning intimacy, privacy, power and control as well as the necessity to reflect on the psychological, emotional, social and cultural perspectives of all the social actors involved. Among other things, our findings showed how it was only by involving older people in the design and development processes of care-related technologies that we could attain productive and successful kinds of mutual inspiration between lay people and technologists. The effective inclusion of older people's perspectives, motivations and thoughts can be crucial in making care-related technologies more acceptable, useable and practical for them, but also in successfully achieving research aims and objectives. In order to be successful, the development of an activity/inactivity-monitoring system must be viewed less as a technological challenge and more as the creation of an integrated *socio-technical system* in which technology is meaningful and purposeful for all the people and organizations involved. In other words, the implementation of these technologies must be conducted in ways which are fully participatory and inclusive for older people, in order to ensure that the systems are designed both *for* and *with* them.

Concluding remarks and final recommendations

This chapter provides a discussion of the concept of *triangulation*, its early definitions and uses, and some of the most relevant theoretical and methodological controversies characterizing its development in the last decades. Even though extremely time-consuming, triangulation is a useful tool to use in qualitative (and quantitative) research so as to increase the validity, credibility and utility of our research findings. Together with this considerable benefit, triangulation can be useful to increase our confidence in data analysis and interpretation, facilitate our sociological imagination (Mills, 1959), foster innovative and creative ways to understand a phenomenon, reveal unexpected findings, challenge or integrate theories, and offer deeper and broader explanations of a phenomenon. Different scholars suggest different interpretations of triangulation, its advantages and potential, and its different types.

While recognizing the utility of further developments and integrations of this concept, this article considers Denzin's original typology an excellent starting point and orienting compass. Back in the 1970s, Denzin described triangulation as combining data, theories, investigators and methods to study the same phenomenon while aiming to overcome incomplete accounts and provide a comprehensive and reliable picture of the phenomenon. He described four types of triangulation: *data triangulation* (the collection of different sets of data in different periods of time and from different sources and places), *theoretical triangulation* (using multiple theories or theoretical frameworks, sometimes from diverse disciplines or areas of knowledge), *investigator triangulation* (the use of different researchers in the study) and *methodological triangulation* (the use of multiple methods to study the same phenomenon). Later on, when reassessing the multiple challenges of triangulation, the author suggests a sort of conceptual mediation aimed at reframing mixed methods research on the basis of critical interpretive methodologies (Denzin, 2012). Notwithstanding some of the key controversies and debates revolving around the nature of mixed methods research, Denzin reiterates his ontological and epistemological stance about the role of the "researcher-as-bricoleur-theorist" working between and within competing perspectives and acting as a catalyst for positive social change.

After having briefly outlined some of the most common uses, abuses and misconceptions of the term triangulation as well as some of the recent debates revolving around it, this article provides two examples of triangulation, making reference to Denzin's typology: the first one combining *theoretical*, *data* and *methodological triangulation*, and the second one including an example of *investigator triangulation*. Both examples refer to the use of triangulation in qualitative research and show how the ways we shape our research is reflected *in* and *by* the ways we shape our realities and how we construct our social worlds. By choosing one theory over another, one set of data over another, and one method over another, not only do we affect the research outcome, its solidity and credibility, but we also contribute to the construction of social reality. Our knowledge, our conceptions and our beliefs of what reality is—and this includes the products of our research—become embedded in the institutional fabric of society. This is why it is important to carefully, critically and reflexively ponder our theoretical and methodological choices, because, through such choices, we all—quite often unconsciously—help recreate dynamics of inclusion and exclusion.

The use of triangulation in qualitative research is a complex, time-consuming and onerous process. It requires the researcher to deal with the complexities and inconsistencies of research outcomes as well as to come to terms with the necessity to produce reliable, credible and solid results. Qualitative research relies upon a careful interpretation of themes, patterns, concepts, categories and narratives, while acknowledging and setting out potential biases and limitations in the context. Producing clear, coherent and convincing interpretations out of complex social realities is one of the problems shared by *all* researchers, not only qualitative ones. In the end, there is no research project that cannot be improved in its accuracy and credibility. As a consequence, we must be aware that what we find is always shaped by us (Marradi, 1988), that it is not the only truth that could be gathered from our data, and that the research methods require an ongoing critical and reflective consideration, the end products of which are never completely faultless. But equally, we should engage in designing research projects where what we construct cannot be seen as

arbitrary but as a truly *valid start* toward challenging conventional interpretations and expanding our current understanding of a phenomenon. The credibility of our findings can thus be solidly grounded both in the careful planning and implementation of the research design and in the multiple methods, theories, data, perspectives and creative tools we use to grasp the phenomenon we want to study. Regardless of what type of triangulation we employ and what level of credibility readers attach to our work, reflecting upon and using triangulation undeniably helps us to initiate a “dialogic relationship” with the “moral community” (Denzin, 2001, p. 43) that, as researchers, we all belong to.

Beyond the above-mentioned challenges and shortcomings, triangulation is an excellent alternative option for validating processes (Denzin and Lincoln, 2011; Denzin, 2012). We can use several strategies to increase the rigor, thoroughness and depth of our research, which include the collection of different theoretical and methodological perspectives, diversification of the empirical materials, and participation of various researchers—possibly with different perspectives—in a single study. This chapter aimed to illustrate some of the most recent debates revolving around the concept of triangulation and show examples of how to increase the quality of our data and interpretations as well as their credibility and reliability through the use of triangulation.

Any study based on a single-method theoretical approach or research technique is undoubtedly more inclined to errors and biases compared to other studies that use multiple ones. Together with the production of more exhaustive, valuable and reliable results, triangulation enables the researcher to dialog with both positivist and constructionist approaches. Ultimately, we should consider that the aim of any type of scientific knowledge is not merely to measure and assess data with the implicit assumption of discovering some universal truths, but rather to understand and grasp reality as something which is also (if not mostly) socially constructed. It is hoped that this chapter can help unravel current conceptual controversies on triangulation, bridge the gap between some of them and provide some suggestions for scholars and young researchers who want to advance existing knowledge and propel new findings in this direction.

Introduction

In some studies, researchers pursue one simple question. This can be a closed question for testing, such as “Does this drug perform better than a placebo?” Or it can be an open question for exploration, such as “Is there a Thyrotropin Releasing Factor?”, which was an important question in the biomedical sciences in the early 1960s (Latour and Woolgar, 1986, p. 147). In contrast, many educational researchers study complex problems in practice. They will investigate various aspects of the problem, considering it from different perspectives of participants such as schoolchildren, teachers, parents, and school leaders. Such educational studies pursue one or more complex questions, which result in one or more answers, inferences, or, to use the technical term of this chapter, *claims*, for each aspect and each different perspective. During such a complex study, those claims are connected into an ever-growing integrated claim, which at the end of the study results in the *final integrated claim*, in mixed methods research usually called the *meta-inference* (Creamer, 2018; Teddlie and Tashakkori, 2009).

One way in which different perspectives on a phenomenon can be obtained is by using multiple methods. Each method provides a unique perspective on the phenomenon; hence, each method can be used to answer a different research question. For instance, questions about teacher behavior can be answered by using video observations, whereas questions about their underlying reasons and motives can be answered through interviews (see Example 1 below). By combining the answers obtained through multiple methods, researchers can obtain a more detailed understanding than would be possible by using one method alone (Greene, 2007, 2015; Flick, 2017; Schoonenboom, 2019; Uprichard and Dawney, 2019).

This chapter discusses how a detailed understanding unfolds in a research study as a result of the various decisions that are made related to the use of multiple methods. Choosing to use multiple methods in a study is not born from one single decision at the beginning of the study, but instead a multi-faceted, multi-step decision that can be repeated throughout a study. The decision process contains three aspects, which together form the basis for this chapter's sections and its decision model (Fig. 1). The first aspect is the nature of the datasets involved, which can be qualitative datasets and/or quantitative datasets. Commonly, a study that includes one or more qualitative and one or more quantitative datasets is called a *mixed methods* study, whereas a study that includes either qualitative datasets or quantitative datasets, but not both, is called a *multimethod* study. The second aspect is the level of the decision, which is either the abstract level of qualitative versus quantitative datasets or the concrete level of specific types of datasets, such as questionnaire data or interview data. The third aspect is the type of decision. A distinction is made between decisions to *collect* data, to *combine* different forms of data collection and the decision to *further develop* collected datasets.

Fig. 1 Six decisions to collect, combine, and develop datasets in mixed methods and multimethod research. (1) Collecting qualitative or quantitative data; (2) Collecting specific kinds of data; (3) Combining qualitative and quantitative data collection; (4) Combining specific kinds of data collection; (5) Further developing qualitative data: quantizing; (6) Further developing qualitative and quantitative data: The mixed dataset.

Sections **Multimethod and mixed methods research** and **The development of an integrated claim using multiple methods** introduce the basic concepts and processes of research using multiple methods. Section **Multimethod and mixed methods research** discusses the difference between multimethod and mixed methods research. Section **The development of an integrated claim using multiple methods** demonstrates a simple multimethod example in which a final integrated claim is developed in two steps. Section **The design decisions: an overview** provides an overview of the design decisions related to the three aspects. In the following sections, decisions are discussed related to collecting data (Section **Decisions related to collecting data**), combining different forms of data collection (Section **Decisions 3 and 4: combining different types of data collection**), and further developing collected datasets (Section **Decisions 5 and 6: further developing collected data**). After the discussion of the decisions, Section **The meta-inference: a real-life example of the development of an integrated claim in mixed methods research** returns to the process that results from these decisions: the development of a final integrated claim, demonstrating how a meta-inference develops in a complex mixed methods example. Section **Conclusion** presents the conclusions.

Multimethod and mixed methods research

As noted in the introduction, research with multiple methods can be divided into *multimethod* research and *mixed methods* research. When two different methods are used, both of which result in distinct qualitative or quantitative datasets, this is known as *multimethod research* (for example, when quantitative test scores are combined with quantitative questionnaires or when qualitative interviews are combined with qualitative observations; see [Example 1](#) below). When two different methods are used—one of which results in one or more quantitative datasets, while the other results in one or more qualitative datasets—this is called *mixed methods research*. An example would be when test scores are combined with interviews (see [Example 2](#) below).

Mixed methods and multimethods research share important characteristics. For instance, obtaining a detailed understanding—typically called a deeper, comprehensive, or fuller understanding—has been recognized as an aim for mixed methods and multimethod research ([Greene, 2015](#); [Flick, 2017](#)). Similarly, including various perspectives is a characteristic of mixed methods research ([Mertens, 2007](#)) and multimethod research ([Flick, 2017](#)). Likewise, as will be explained in more detail later, abduction—the pattern of contradiction → explanation—is generally a characteristic of research with multiple methods ([Schoonenboom, 2022](#)), including but not limited to mixed methods research ([Morgan, 2007](#); [Wheeldon, 2010](#)) [See for an extension of these arguments to complex research generally, including mono-method research, [Denzin \(1978\)](#), [Reichert \(2014\)](#), [Sandelowski \(2014\)](#), and [Schoonenboom \(2022\)](#)].

Despite these fundamental resemblances, Section **Decisions related to collecting data** will show that some possible uses are unique to qualitative datasets, whereas others are unique to quantitative datasets. As a result, multimethod research can be used to answer a broader array of research questions than mono-method research, and mixed methods research can respond to an even broader array of research questions than multimethod research. Of course, this does not mean that conducting a mixed methods study is always preferable to multimethod research, just as it is not always appropriate to conduct a complex, multi-faceted study instead of investigating a singular question.

In this chapter, I use the term *research with multiple methods* as the overall term. I use the term *mixed methods* to refer to a study that includes both qualitative and quantitative methods and data, and I use the term *multimethod* for a study that includes the use of two or more qualitative methods or two or more quantitative methods, but not both types of methods. I am well aware that this is just one of the various ways in which the distinction between *multimethod* and *mixed methods* research has been drawn in the mixed methods literature (see [Box 1](#) below).

Box 1

In the mixed methods literature, the terms *mixed methods* and *multimethod* have various yet related meanings (for a historical and comprehensive overview, see Anguera et al., 2018). Different authors have emphasized different aspects of mixed methods and multimethod research, drawing different distinctions between them. Historically, the term *multimethod* came first: Brewer and Hunter (1989) used the term *multimethod* to refer to the use of more than one method in a study, including what I call mixed methods and multimethod research.

In the 1990s, the term *mixed methods* came to the fore, indicating the use of both quantitative and qualitative methods in one study. As a result, the term *multimethod* acquired a second meaning. Some authors continue to use the term *multimethod* to refer to any study in which multiple methods are used, including mixed methods studies (Hunter and Brewer, 2015; Plano Clark and Ivankova, 2016). Others specify a distinction between *mixed methods studies*, which involve quantitative and qualitative methods, and *multimethod studies*, which involve the use of two qualitative methods or two quantitative methods, but not both (Hesse-Biber, 2010; Creswell, 2014; Tashakkori et al., 2021).

A hallmark of mixed methods research is integration: bringing together quantitative and qualitative components—that is, the data and/or their results. As integration rose to prominence, the term *mixed methods* took on another meaning of its own. Some authors refer to a *mixed methods study* as one in which the qualitative and quantitative components are integrated (Creswell, 2014; Anguera et al., 2018), while others consider a study in which such integration lacks a *multimethod study*, even if both quantitative and qualitative data are used (Bazeley, 2018). For some authors, using qualitative and quantitative data is a requirement for a *mixed methods study*; for others, any study in which two or more methods are integrated can be called mixed methods research (Morse and Niehaus, 2009; Bazeley, 2018).

The development of an integrated claim using multiple methods

The aim of research using multiple methods is to obtain a more detailed understanding than would be possible using one method alone (Greene, 2007, 2015; Flick, 2017; Schoonenboom, 2019; Uprichard and Dawney, 2019). This detailed understanding becomes visible in an integrated claim, and this section demonstrates how an integrated claim is developed using multiple methods. Example 1 is a multimethod study by Finlay et al. (2015):

Example 1. Finlay et al. (2015) investigated the delivery of sexual health education to young people with intellectual disabilities. One of the study's foci was how educators anticipate problems of comprehension and how they act when a learner shows a lack of comprehension. Finlay et al. (2015) made use of two different qualitative methods. To investigate educators' behavior, they conducted and analyzed video observations; to learn more about the views that motivate their behavior, they conducted and analyzed semi-structured interviews. According to their discussion:

It seemed to be the case that the best evidence of comprehension was produced at first attempts, and rarely seemed convincing if it was the product of challenge and correction. In the examples here, the learner eventually offers the 'correct' response, and the leader then moves on to the next activity. A superficial resolution is achieved. We can understand this pragmatic approach in terms of both the models of understanding offered by the educators, whereby development of comprehension is nonlinear, and learners are only expected to pick up 'bits,' and by the immediate demands of the situation, in that there are other group members to consider and an agenda of activities to get through in the allotted time (p. 336).

As a result of incorporating the different datasets, the authors were able to develop a final integrated claim, as displayed in Table 1 (based on a format in Schoonenboom, 2022). Table 1 shows how an integrated claim develops. The authors used two qualitative methods of data collection, video observations and interviews, which resulted in two types of qualitative data: video recordings and interview transcripts, from which the authors derived Claims [1], [2] and [4], which were subsequently integrated into integrated claims (IC) [3] and [5].

Example 1 demonstrates the various characteristics of research with multiple methods. First, the development of the conclusion from start to finish involves the use of multiple methods, in this case, two qualitative methods, video observations and interviews; therefore, Example 1 is a multimethod study. Second, the conclusion—(IC) [5]—is not a simple claim; rather, it comprises three simple claims, [1], [2], and [4], which are all interconnected. Third, IC [5] is not created by simply combining claims [1], [2], and [4] in one step; instead, it is developed over several steps that build on each other (two steps in this case). In Step I, simple claims [1] and [2] are integrated into a complex claim, IC [3]; in Step II, IC [3] and simple claims [4] are integrated to form the conclusion, IC [5]. Fourth, each integration step can be assigned a label depending on the methods involved in deriving its claims. In this case, Step II is decisive for calling the research wholly multimethod because it integrates claims derived from two different qualitative datasets, observations, and interviews and is therefore labeled *multimethod*. Step I is labeled *mono-method* because it integrates claims derived from using only one type of data, the video observations.

Fifth, these two steps display a pattern. Step I results in a contradiction: "Evidence of comprehension produced at first attempts was convincing, *but* evidence of comprehension that was the result of challenge and correction was superficial." This contradiction is then resolved in Step II: "Evidence of comprehension produced at first attempts was convincing, *but* evidence of comprehension that was the result of challenge and correction was superficial, *because* educators did expect comprehension to slowly develop, and they wanted to give attention to all pupils." This pattern of contradiction, followed by an explanation, is a hallmark of research with multiple methods. It is generally known as *abduction* (Hoffmann, 1999; Reichertz, 2014) and is considered essential to mixed

Table 1 Development of a final integrated claim in Example 1.

Methods	Obtained claims	Integrated claim	Connection
I. Mono-method (qualitative)			
Video observations	→ [1] Evidence of comprehension produced at first attempts was convincing.	IC[3] Evidence of comprehension produced at first attempts was convincing, but evidence of comprehension that was the result of challenge and correction was superficial.	Contradiction
Video observations	→ [2] Evidence of comprehension that was the result of challenge and correction was superficial.		
II. Multimethod (qualitative)			
Video observations	→ IC[3] Evidence of comprehension produced at first attempts was convincing, but evidence of comprehension that was the result of challenge and correction was superficial.	Final integrated claim IC[5] Evidence of comprehension produced at first attempts was convincing, but evidence of comprehension that was the result of challenge and correction was superficial, because educators did expect comprehension to slowly develop, and they wanted to give attention to all pupils.	Explanation
Interviews	→ [4] Educators did expect comprehension to slowly develop, and they wanted to give attention to all pupils.		

Note. IC = integrated claim.

methods research (Morgan, 2007; Wheeldon, 2010). As one of the main rationales for conducting mixed methods research, it is also called *initiation* (Greene et al., 1989).

The design decisions: an overview

For claims to be derived and integrated, researchers make various decisions regarding the use of multiple methods in a study, as shown in Fig. 1. Fig. 1 shows that researchers make decisions on data collection on the abstract level of quantitative and qualitative data (Decisions 1 and 3) and at the level of specific data collection methods (Decisions 2 and 4). They make these decisions both related to the data to be collected separately (Decisions 1 and 2) and to their combination (Decisions 3 and 4). Finally, once data have been collected, researchers can decide to further develop their datasets into additional datasets (Decisions 5 and 6). These six decisions are discussed below.

Decisions related to collecting data

Decision 1: collecting qualitative and/or quantitative data

Depending upon their goals, mixed methods and multimethod researchers collect quantitative and/or qualitative datasets. The difference between quantitative and qualitative datasets is best captured by the labels *structured* and *unstructured* (Ahuja et al., 2020). Quantitative data are structured data that can be represented as numbers (Onwuegbuzie and Leech, 2019; Nzabonimpa, 2018; Sandelowski et al., 2009). They consist of variables and their values collected in a fixed structure, usually a table. In contrast, qualitative datasets are unstructured; they are non-numerical data of various types, such as text, video, audio, drawings, or material objects. As a result of this difference, qualitative and quantitative data partly differ in what researchers can use them for, which forms the basis for the decision on whether to include qualitative and/or quantitative data in their studies:

Possibilities of Qualitative Data

- Discover unknown themes and relations, including reasons, motives, and causal relations.
- Establish the influence of context on causal relations.
- Reveals patterns in the research data.
- Develop narratives of experiences and events in detail.

Possibilities of Quantitative Data

- Describe statistics at the group level and provides an overview.
- Uncover patterns among known variables.
- Provide quick diagnostics of individuals.
- Identify deviating individuals quickly.
- Establish overall effects (causal relations) in larger groups.
- Establish differences between groups.
- Establish the influences of known context variables on causal relations in larger groups.
- Construct narratives among known variables in larger groups.

As these lists make clear, both qualitative and quantitative data can be used to discover and/or test causal relations (Maxwell, 2019) and to establish the influence of context. In quantitative research, this is called moderation, and the influencing factor is termed a moderating factor (Hayes, 2017).

Both types of data can also be used to discover new patterns (Glaser, 2008) and construct narratives. Note, however, that newly discovered patterns in a quantitative dataset are necessarily based on the existing variables and their values—they are all the researcher has—whereas from a qualitative dataset, completely new “variables”, or “themes”, may arise.

Both types of data allow the construction of narratives. Using qualitative data, a researcher can construct detailed narratives that show how one event leads to another, what the motives of those involved are, and how the development of events is influenced by context. By coding the absence and presence of specific events, quantitative data allow us to determine which combinations of events, and hence which narratives, are likelier to occur. Various mixed methodologies transform qualitative data to construct such quantitative narratives, a transformation that will be explained in more detail in section **Quantitizing: converting qualitative data into quantitative data**. Example methodologies include Qualitative Comparative Analysis (QCA; Rihoux and Ragin, 2009) and multiple-case narratives (Abbott, 1992; for an example, see Abbott and Hrycak, 1990).

Quantitative data can be used for quick diagnostics and identification at the group and individual levels, based on the values of specific variables. This includes descriptive statistics—that is, a quick overview of a group with respect to a selection of known variables—as well as the calculation of effects and effect sizes. An important function of quantitative variables in mixed methods research is creating groups, allowing researchers to explore differences between experimental and control groups, for example.

Decision 1: What are your goals as a researcher? What type of data (quantitative or qualitative) could you use to reach your goals?

Decision 2: collecting specific types of data

The general properties of qualitative and quantitative data in the previous section can help researchers decide whether they want to include qualitative and/or quantitative data in their studies. Even more important is the decision on what specific data to collect and which specific methods to use. In **Example 1**, the qualitative data generated by classroom video observations allowed researchers to investigate pupils’ and teachers’ behaviors, but they could not tell them anything about the teachers’ ideas and motives behind these behaviors, whereas interviews allowed the researchers to investigate teachers’ ideas and motives, but were unable to show actual behavior. Both the methods and the generated datasets were qualitative, but the types of claims that researchers can draw from them are different.

Similarly, in multimethod quantitative research, differences in test scores can tell the researcher something about whether a classroom intervention had an effect, but they cannot tell the researcher about how learners experienced the intervention, while questionnaires can tell the researcher about how learners experienced the interventions, but they do not show the researcher their test results. In this case, the methods used are both quantitative, but the types of conclusions that researchers can draw from them are different.

Decision 2: What specific methods will you include for which specific purpose?

Decisions 3 and 4: combining different types of data collection

Having seen how qualitative and quantitative data can be applied to different uses, the next question is why researchers want to combine them in a single study. As stated above, the decision to combine methods can be situated both at the abstract level of combining qualitative and quantitative datasets (Decision 3 in **Fig. 1**) and at the level of the specific methods of data collection (Decision 4 in **Fig. 1**). This section will discuss Decisions 3 and 4 concurrently, using real-life examples from educational research. The real-life examples all involve mixed methods research and show the advantages of combining quantitative and qualitative datasets. In general, two reasons for combining can be distinguished: one is combining qualitative and quantitative data collection and data analysis (Section **Integrating outcomes of the analysis of separate datasets**); the other is using one type of data as an “add-on” to a study of the other type (Section **Using quantitative data for development in a qualitative study (and vice versa)**).

Integrating outcomes of the analysis of separate datasets

In a mixed methods study, qualitative data and quantitative data can be collected separately, and the resulting qualitative and quantitative datasets can each be subjected to their own types of data analysis. This is the “prototypical” mixed methods study: It is the type of study on which the three widely-used “core designs” of Creswell and Plano Clark (2018) are based. Such a prototypical mixed methods study can be conducted for various reasons. Some examples are presented below.

To apply themes discovered in interviews for generalization in a quantitative study

Mitchell Fuentes (2008) conducted in-depth life history interviews with an ethnically diverse convenience sample of 28 women with at least one experience of sexual abuse. The study revealed that depression was a main risk factor that connected sexual abuse to an increased risk of sexually transmitted infections. A questionnaire among a larger sample of women (with and without experience of abuse) largely confirmed these findings.

In this example, including qualitative data made it possible for Mitchell Fuentes to discover an unknown causal pattern between partly unknown risk factors. Subsequently, quantitative data collection widened the field of research and allowed the pattern to be tested. This would have been much more difficult to achieve without quantitative data collection. Equally, the larger sample afforded by the quantitative data collection allowed for a comparison between women with and without experience of sexual abuse. Related to the specific methods, both qualitative interviews and quantitative questionnaires allow people to express their experiences and opinions. Therefore, combining them made it possible to use quantitative questionnaires to generalize the qualitative findings.

To provide a quantitative overview as part of qualitative research

Varshney (2001) set out to better understand Hindu–Muslim violence in India. Although much of the resulting research is based on interviews with Hindus and Muslims, Varshney started with the question, “Where and when did Hindu–Muslim riots in India between 1950 and 1995 take place?” To answer this question, he used quantitized data derived from riot reports in the *Times of India*. By attaching the labels *place* and *time*, as well as derivatives such as *province* and *urban* vs. *rural*, Varshney was able to compile a geographical and chronological overview of Hindu–Muslim violence in this place. His findings highlighted how riots had hardly occurred at all in rural areas and that there were significant differences between cities.

In this example, the researcher could not have obtained such an overview from the interview data alone. Without the additional collection of data and its subsequent quantization, this overview would not have been possible. More specifically, whereas quantitized data from riot reports could provide an overview of where and how often riots took place, qualitative interviews could be used to obtain a detailed insight into the experiences and dynamics of Hindu–Muslim riots. In combination, quantitized data from riot reports allowed researchers to create a set of cities with different levels of riot-proneness from which to draw a heterogeneous sample for their interviews.

To further explore differences between quantitative groups or deviating individuals

Using data from a questionnaire among teaching staff at one university, Schoonenboom (2016) identified one department in which the digital learning environment Blackboard was used more often than in the other departments. Interviews with Blackboard organizers revealed that this was the only department where the use of Blackboard was compulsory and where Blackboard forums were prestructured to guide discussions among students.

Here, quantitative data collection and data analysis allowed the researcher to quickly identify variables from which (in this case) the teaching staff in one department deviated. Qualitative data about how Blackboard was organized was needed because organizing Blackboard was evidently a complex process, with many unknowns that could not be adequately captured by a pre-structured questionnaire. At a more specific level, quantitative questionnaires allowed a large group of teachers from different departments to indicate how often they used Blackboard, whereas qualitative interviews allowed Blackboard organizers to explain how they organized the use of Blackboard and why. In combination, the identification of a deviating department using the quantitative questionnaire allowed researchers to investigate differences between this department and other departments in their interviews.

To further explore any expected or unexpected quantitative results using qualitative data collection and analysis

Using a questionnaire, Ivankova and Stick (2007) discovered that the factors contributing to students’ persistence in higher education were *program*, *online learning environment*, *student support services*, *faculty*, and *self-motivation*. They conducted interviews with typical respondents to explore the results in greater depth. Four major themes emerged: (1) quality of academic experiences, (2) online learning environment, (3) support and assistance, and (4) student self-motivation.

By using quantitative data collection and data analysis, Ivankova and Stick (2007) were able to obtain a topical overview of a larger group of students and ascertain the extent to which known factors and their interactions contributed to their persistence in higher education. Through their use of quantitative data collection and analysis, they were able to discover themes related to persistence in higher education. At a more specific level, quantitative questionnaires allowed students to express how they valued the program, online learning environment, student support services, and the faculty while at the same time allowing researchers to correlate their judgments’ values. Qualitative interviews allowed the students to elaborate on these factors, thereby allowing the researchers to validate them and understand them in more depth. In combination, through their

qualitative interviews, they were able to refine their quantitative findings and discover the processes underpinning the initial questionnaire responses.

Using quantitative data for development in a qualitative study (and vice versa)

In addition to analysis, qualitative and quantitative datasets can also be used as an add-on to another study. This is a broad category of all uses of datasets in which data are not used to derive claims. This includes, but is not limited to, the use of a dataset of one type to develop a study with a dataset of the other, also called *development* (Greene et al., 1989).

I will discuss two uses of data as an add-on here. The first is the use of quantitative data and datasets for sampling. For example, researchers can use tests (e.g., standardized tests) to select a sample of participants for further research. They do so by selecting participants who show specific values for one or more variables.

To use quantitative data for sampling for qualitative data collection

Visser et al. (2018) used a questionnaire to identify students with high, middle, and low levels of procrastination and then selected students from these three groups for an interview.

Visser et al. (2018) used quantitative data to provide a quick diagnosis of individuals, and they used qualitative data to develop narratives of experiences and events of procrastination. At the level of the specific methods, questionnaires about procrastination allowed students to assess their different procrastination behaviors and experiences and allowed researchers to assess the level of procrastination of each student. Interviews allowed students to express their experiences with procrastination and researchers to discover patterns in the students' narratives. As a combination, the selection of students based on their quantitative level of procrastination allowed researchers to investigate the "worlds" of students with high, middle, and low levels of procrastination in more depth in their interviews.

In mixed methods research, quantitative data are often used for sampling. In the various examples above, quantitative data were used to select (a) students with different levels of procrastination for an interview (Visser et al., 2018); (b) cities in India with varying rates of riot violence for further exploration (Varshney, 2001); (c) departments in which to explore the organization of Blackboard (Schoonenboom, 2016); and (d) students to interview about their persistence in higher education (Ivanova and Stick, 2007).

To use qualitative data to illustrate quantitative findings

In this case, the function of the illustration is to further the reader's understanding by highlighting how the conclusion plays out in practice, in a specific real-life case. This is also called "putting 'meat on the bones' of 'dry' quantitative findings" (Bryman, 2006, p. 106).

Decisions 3 and 4: What are your motives or reasons for including both qualitative and quantitative data? What are your motives or reasons for including the specific types of data that you want to combine in your study (observations, interviews, test scores, questionnaire data, etc.)?

Decisions 5 and 6: further developing collected data

Quantitizing: converting qualitative data into quantitative data

When a mixed methods researcher uses both a quantitative dataset and a qualitative dataset, this does not necessarily mean that he or she carried out both qualitative and quantitative data collection. In fact, quantitative datasets can also be obtained by *quantitizing* collected qualitative data—that is, by creating a quantitative dataset from a qualitative one. This is often called "converting" qualitative data into quantitative data (Nzabonimpa, 2018; Onwuegbuzie and Leech, 2019).

The quantization procedure is as follows: Qualitative researchers often use codes to denote fragments of, for example, text data or video data. In qualitative data analysis, these codes can be used to find and analyze the fragments attached to them. The unit of a code with its fragment remains qualitative, unstructured data: The fragments are unstructured, and it is the fragments that are analyzed in qualitative data analysis, not the codes.

However, it is also possible to separate the codes from their corresponding fragments. In doing so, the codes are *quantitized*; they become quantitative data, which can then be stored in a list or table. Lists of quantitized codes can then be subjected to quantitative analysis, for example, by counting the number of specific codes (Sandelowski, 2014). Below is a real-life example (discussed in Bazeley, 2012) in which qualitative data are quantitized:

Kaplun (2012) studied the experiences of 188 families from a disadvantaged area in Australia with their child's transition to school. The researcher conducted semi-structured interviews with the parents before and after the transition. She asked them to describe their own experiences and those of their children, including activities they thought their child would enjoy and/or do well in at school. By counting, comparing, and classifying the activities mentioned in the interviews, Kaplun was able to show that the number of parents who said their child enjoyed or was good at a specific activity declined during the child's transition to school for arts-related activities such as dancing, singing, painting, and drawing, whereas it remained constant for academic activities.

Decision 5: Do you intend to quantitize your qualitative data? If so, for what purpose?

The mixed dataset

A second possibility for further developing collected datasets is by bringing the collected qualitative and quantitative data together into a mixed dataset. A mixed dataset has a structure similar to that of a quantitative dataset, namely a table. One or more columns of a mixed table will contain structured data (either numerical values or codes) derived either directly from quantitative data collection or by quantizing qualitative data. In addition, one or more columns will contain unstructured data, most typically text fragments. The process of creating a mixed dataset is also called *data consolidation* (Caracelli and Greene, 1993; Vogl, 2019).

In mixed data analysis, researchers analyze the structured and unstructured data jointly in a mixed dataset. Mixed datasets can be used to explore any types of differences and resemblances between qualitative and quantitative data. In a mixed dataset, researchers combine the possibilities of qualitative and quantitative data. For example, they can use the quantitative data to uncover patterns among the variables and then consider the qualitative data to see if these corroborate the patterns, reveal additional aspects, or provide additional insights.

The quantitative data in a mixed table are well suited to create groups among the qualitative data. This principle is used for data analysis in the case comparison table (Schoonenboom and Johnson, 2021), in which the values of the quantitative data are used to sort and re-sort the data, create groups, and inspect the qualitative data for each group separately, with the aim of identifying similarities within and differences between groups. As the analysis proceeds, more quantitative diagnostic codes are developed until subgroups that are discrete and make sense have been identified, which may potentially provide an explanation for the differences between groups. The example used by Schoonenboom and Johnson (2021) is presented here as Example 2.

Example 2. Schoonenboom and Johnson (2021) used quantitative and qualitative data published in Lee and Greene (2007), a study on the relationships between the language problems of international students and their grade point average (GPA) in their first semester at one university in the US. Schoonenboom and Johnson (2021) created a simple table containing one record for each student, along with their language score, GPA, and a quote from their interview, which could then be sorted and resorted to uncover patterns. One specific group of four students emerged. Despite their language problems, members of this group still obtained the highest GPA. The quotes show that three of the four students in this group referred to compensation strategies, while none of the students with language problems and less than the highest possible GPA did so. In this way, Schoonenboom and Johnson (2021) were able to formulate a hypothesis for further research: Language problems affect international students' GPA unless they deliberately use compensation strategies.

Whereas the quantitative data are used to create the groups initially, the qualitative data are then explored for often unidentified points of differences between the groups, as well as for identifying the reasons or causes for these differences. As a result, mixed data analysis is particularly suited to discovering and exploring moderation, as highlighted in Example 2: Schoonenboom and Johnson (2021) formulated an effect ("language problems affect international students' GPA") that is moderated by the factor *compensation strategies* ("unless they deliberately use compensation strategies").

Decision 6: Do you intend to bring your quantitative and qualitative data together in a mixed dataset? If so, for what purpose?

The meta-inference: a real-life example of the development of an integrated claim in mixed methods research

Section **The development of an integrated claim using multiple methods** demonstrated the development of a final integrated claim in a simple, multimethods example, Example 1. Now, at the end of the chapter, it is time to show the development of an integrated claim in a complex mixed methods example. Table 2 shows the integration process in Example 2.

Table 2 contains three steps: Step I is the main conclusion by Lee and Greene (2007), while Steps II and III stem from the reanalysis by Schoonenboom and Johnson (2021). Similar to Table 1, Lee and Greene's conclusions were more complex, but the majority have been omitted as they did not play a role in the reanalysis.

The integration process in mixed methods Example 2 is the same as in multimethod Example 1. First, its conclusion, integrated claim (IC) [8], is not a simple claim; rather, it contains five simple claims [1], [2], [4], [6], and [7] that are interconnected. Second, this conclusion is not created by combining the five simple claims in one step, but over several steps (three in this case) that build on each other. In Step I, claims [1] and [2] are integrated into a complex claim, IC [3]. In Step II, claims [2] and [4] are integrated into a complex claim, IC [5]. In Step III, claims [4], [6], and [7] are integrated to form the integrated inference, IC [8]. Third, these steps can be assigned a label depending on the number and types of methods involved in deriving their claims. In this case, all three steps are labeled *mixed methods* because all steps involve either a qualitative and a quantitative dataset (Step I) or a mixed dataset (Steps II and III). Fourth, these steps follow the same pattern of contradiction followed by an explanation. In Steps I and II, two different contradictions are developed, both of which are resolved in Step III: Some students had a maximum GPA despite less than perfect English skills *because* they possessed compensation strategies. This integrated inference explains both why English skills still affect

Table 2 Development of an integrated inference in [Example 2](#).

Methods	Obtained claims	Integrated claims	Connection
I. Mixed methods			
Quantitative questionnaire	→ [1] Nonsignificant correlations were found between test scores and GPA.	IC [3] Although nonsignificant correlations were found between test scores and GPA, qualitative findings indicated that English skills are an important factor affecting students' course performance (Lee and Greene, 2007).	Contradiction
Interviews	→ [2] English skills are an important factor affecting students' course performance.		
II. Mixed methods			
Interviews	→ [2] English skills are an important factor affecting students' course performance.	IC [5] Although English skills are an important factor affecting students' course performance, some students had a maximum GPA despite less than perfect English skills.	Contradiction
Quantitative data	→ [4] Some students had a maximum GPA despite less than perfect English skills.		
III. Mixed methods			
Quantitative data	→ [4] Some students had a maximum GPA despite less than perfect English skills.	Integrated inference IC [8] Some students had a maximum GPA despite less than perfect English skills because they possessed compensation strategies.	Explanation
Mixed data	→ [6] Three out of four of these students mentioned compensation strategies in their interviews.		
Mixed data	→ [7] None of the students with less than perfect English skills and a less than maximum GPA mentioned compensation strategies.		

GPA (contradiction of Step I) and why some students, despite less than perfect English skills, nonetheless obtained the highest GPA possible (contradiction of Step II).

Yet, at the same time, [Example 2](#) also highlights the advantages of combining qualitative and quantitative datasets. Claim [1] shows the benefits of including quantitative data. Analysis of this data in [1] showed that, for this sample, language problems did not affect the students' GPA (i.e., establishing overall effects—causal relations—with larger groups). This was an important conclusion, as it set the stage for both [Lee and Greene \(2007\)](#) and [Schoonenboom and Johnson \(2021\)](#) to ask the question, 'Why?' Without the quantitative data, this question would not have arisen. The quantitative data were then used by [Lee and Greene \(2007\)](#) to identify students whose performance had been affected by language problems as well as those for whom this was not the case (i.e., identifying deviating individuals quickly). Next, it was only through analysis of the qualitative data that [Lee and Greene \(2007\)](#) were able to show that language problems had an effect on individual students (i.e., discovering unknown themes and relations, including causal relations). The researchers were then able to use extreme case analysis to explain the lack of a quantitative effect, whereby variations in students' views of academic success and their perceived levels of background knowledge can help explain their low GPAs relative to their CEEPT scores ([Lee and Greene, 2007](#), p. 366).

At the beginning of their reanalysis, [Schoonenboom and Johnson \(2021\)](#) returned to the quantitative data. Whereas [Lee and Greene \(2007\)](#) mainly focused on individuals, [Schoonenboom and Johnson \(2021\)](#) identified a group of students who, despite having less than perfect English language skills, still managed to achieve the maximum GPA (i.e., establishing differences between groups). In [6], [Schoonenboom and Johnson \(2021\)](#) created a mixed dataset, showing that three of these four students mentioned compensation strategies in their interviews (i.e., identifying and exploring differences between subgroups). Finally, in [7], [Schoonenboom and Johnson \(2021\)](#) observed in their mixed dataset that none of the students with language problems and a less than perfect GPA mentioned such compensation strategies, which enabled them to formulate a hypothesis in [8] that some students had a maximum GPA despite less than perfect English skills *because* they possessed compensation strategies (i.e., uncovering context influences on causal relations between subgroups).

Conclusion

In this chapter, I describe mixed methods research and multimethod research as forms of research with multiple methods. Mixed methods and multimethod research are members of the same family: research that results in a final integrated claim developed from various claims and integrated claims. Mixed methods and multimethod research share the same structure and process of deriving claims through the analysis of empirical data and integrating these claims one by one. In this process, the abductive pattern of contradiction→explanation plays an important role, as seen in both multimethod [Example 1](#) and mixed methods [Example 2](#).

The implication of these commonalities is that abduction is not a specific characteristic of mixed methods research (see for a different view [Morgan, 2007](#)). Rather, as [Example 1](#) has shown, it is a characteristic of research with multiple methods more generally (for abduction in qualitative research, see [Reichert, 2014](#)). This also means that, rather than being one of the reasons for conducting mixed methods research, the contradiction→explanation pattern is an integral part of mixed methods research.

On the other hand, mixed methods research represents a special form of research with multiple methods, characterized by a combination of qualitative and quantitative data, which are fundamentally different. Structured quantitative data can be subjected to quantitative data analysis: Occurrences of specific values can be counted, effects can be calculated, and so on; quantitative data, on the contrary, cannot be used to discover completely new variables. Unstructured qualitative data can be subjected to qualitative data analysis, whereby more complex meanings are derived over several rounds of analysis. However, they cannot be counted or used for selection. By combining both types of data, the mixed dataset allows researchers to explore unknown differences (in the qualitative data) among emerging groups (identified by the quantitative data).

At the level of claim derivation, there is a clear overlap between what researchers can do with qualitative and quantitative data. Both types of data can be used to establish causation, construct narratives or discover moderation. Thus, instead of being different approaches at a higher level, *quantitative* and *qualitative approaches* refer to different types of datasets at a lower level. This shift of the fundamental differences between qualitative and quantitative—from the level of approaches to the level of data—has implications for how researchers should describe mixed methods research. Rather than saying that they used a qualitative and quantitative approach, researchers should describe what they do in terms of the use of qualitative, quantitative and mixed datasets and data analysis. For example:

- We used the quantitative dataset to draw a sample for the interviews, which generated a qualitative dataset, which we then analyzed thematically.
- We quantitized the qualitative interview data, thereby creating a quantitative dataset.
- In a mixed table analysis, we explored the differences between groups in how they responded.

In line with this, researchers should connect other aspects of mixed methods research to what they actually do with their data and not to quantitative or qualitative approaches in general. Validity criteria provide an excellent example of this. Researchers cannot say that they had to obtain a large sample size because they used a quantitative approach. This is because the sample size requirements for a quantitative dataset differ widely, depending on whether the dataset is used to establish an effect, to select individuals, to describe a sample or as part of a mixed dataset.

What about the implications for mixed methods design? Of the six design decisions, four could be considered strategies for mixed methods research because they involve a combination of qualitative and quantitative data: combining qualitative and quantitative data collection and data analysis; using data as an add-on; quantitizing qualitative data; and creating and analyzing mixed datasets. An important characteristic of these four strategies is that, in mixed methods research, they are, and should be, combined. Mixed methods researchers do not choose between these four strategies; they use each of them as and when needed to develop claims and to find and resolve contradictions (see [Schoonenboom, 2019](#)). Thus, in mixed methods research, quantitative data are often used not only for analysis, but for sampling as well. Equally, a mixed methods analysis is often conducted in addition to analyzing the qualitative and quantitative data separately, while qualitative data are often quantitized as well as analyzed ([Sandelowski, 2014](#)).

Significantly, this approach to mixed methods design differs in several respects from research design typologies, as exemplified by [Creswell and Plano Clark \(2018\)](#). Design typologies assume that mixed methods researchers choose between designs based on how the separate strands of qualitative and quantitative data collection and analysis are combined. In doing so, they hide the similarity of the integration process in research with multiple methods generally and the way in which, in good mixed methods research, several of the four strategies are combined. This is not to say that the authors are unaware of these four strategies, only that they are not visible in the design typologies.

Like the illness of atherosclerosis in philosopher [Mol's \(2002\)](#) brilliant book, the decision to include multiple methods in a study is complex and multiple. I hope that this chapter has inspired researchers to navigate this complexity and multiplicity in a productive way.
